

Problem 3.1

[Difficulty: 2]

3.1 Because the pressure falls, water boils at a lower temperature with increasing altitude. Consequently, cake mixes and boiled eggs, among other foods, must be cooked different lengths of time. Determine the boiling temperature of water at 1000 and 2000 m elevation on a standard day, and compare with the sea-level value.

Given: Pure water on a standard day

Find: Boiling temperature at (a) 1000 m and (b) 2000 m, and compare with sea level value.

Solution:

We can determine the atmospheric pressure at the given altitudes from table A.3, Appendix A

The data are

Elevation (m)	p/p_o	p (kPa)
0	1.000	101.3
1000	0.887	89.9
2000	0.785	79.5

We can also consult steam tables for the variation of saturation temperature with pressure:

p (kPa)	T_{sat} ($^{\circ}\text{C}$)
70	90.0
80	93.5
90	96.7
101.3	100.0

We can interpolate the data from the steam tables to correlate saturation temperature with altitude:

Elevation (m)	p/p_o	p (kPa)	T_{sat} ($^{\circ}\text{C}$)
0	1.000	101.3	100.0
1000	0.887	89.9	96.7
2000	0.785	79.5	93.3

The data are plotted here. They show that the saturation temperature drops approximately $3.4^{\circ}\text{C}/1000$ m.

Problem 3.2

[Difficulty: 2]

3.2 Ear “popping” is an unpleasant phenomenon sometimes experienced when a change in pressure occurs, for example in a fast-moving elevator or in an airplane. If you are in a two-seater airplane at 3000 m and a descent of 100 m causes your ears to “pop,” what is the pressure change that your ears “pop” at, in millimeters of mercury? If the airplane now rises to 8000 m and again begins descending, how far will the airplane descend before your ears “pop” again? Assume a U.S. Standard Atmosphere.

Given: Data on flight of airplane

Find: Pressure change in mm Hg for ears to “pop”; descent distance from 8000 m to cause ears to “pop.”

Solution:

Assume the air density is approximately constant from 3000 m to 2900 m.
From table A.3

$$\rho_{SL} = 1.225 \frac{\text{kg}}{\text{m}^3}$$

$$\rho_{\text{air}} = 0.7423 \cdot \rho_{SL}$$

$$\rho_{\text{air}} = 0.909 \frac{\text{kg}}{\text{m}^3}$$

We also have from the manometer equation,

$$\Delta p = -\rho_{\text{air}} \cdot g \cdot \Delta z \quad \text{and also}$$

$$\Delta p = -\rho_{\text{Hg}} \cdot g \cdot \Delta h_{\text{Hg}}$$

Combining
$$\Delta h_{\text{Hg}} = \frac{\rho_{\text{air}}}{\rho_{\text{Hg}}} \cdot \Delta z = \frac{\rho_{\text{air}}}{SG_{\text{Hg}} \cdot \rho_{\text{H}_2\text{O}}} \cdot \Delta z$$

$$SG_{\text{Hg}} = 13.55 \text{ from Table A.2}$$

$$\Delta h_{\text{Hg}} = \frac{0.909}{13.55 \times 999} \times 100 \cdot \text{m}$$

$$\Delta h_{\text{Hg}} = 6.72 \cdot \text{mm}$$

For the ear popping descending from 8000 m, again assume the air density is approximately constant, this time at 8000 m.
From table A.3

$$\rho_{\text{air}} = 0.4292 \cdot \rho_{SL}$$

$$\rho_{\text{air}} = 0.526 \frac{\text{kg}}{\text{m}^3}$$

We also have from the manometer equation

$$\rho_{\text{air}8000} \cdot g \cdot \Delta z_{8000} = \rho_{\text{air}3000} \cdot g \cdot \Delta z_{3000}$$

where the numerical subscripts refer to conditions at 3000m and 8000m.
Hence

$$\Delta z_{8000} = \frac{\rho_{\text{air}3000} \cdot g}{\rho_{\text{air}8000} \cdot g} \cdot \Delta z_{3000} = \frac{\rho_{\text{air}3000}}{\rho_{\text{air}8000}} \cdot \Delta z_{3000} \quad \Delta z_{8000} = \frac{0.909}{0.526} \times 100 \cdot \text{m} \quad \Delta z_{8000} = 173 \text{ m}$$

Problem 3.3

[Difficulty: 3]

3.3 When you are on a mountain face and boil water, you notice that the water temperature is 195°F. What is your approximate altitude? The next day, you are at a location where it boils at 185°F. How high did you climb between the two days? Assume a U.S. Standard Atmosphere.

Given: Boiling points of water at different elevations

Find: Change in elevation

Solution:

From the steam tables, we have the following data for the boiling point (saturation temperature) of water

$T_{\text{sat}} (^{\circ}\text{F})$	p (psia)
195	10.39
185	8.39

The sea level pressure, from Table , is

$p_{\text{SL}} = 14.696$ psia

Hence

$T_{\text{sat}} (^{\circ}\text{F})$	p/p_{SL}
195	0.707
185	0.571

From Table

p/p_{SL}	Altitude (m)	Altitude (ft)
0.7372	2500	8203
0.6920	3000	9843
0.6492	3500	11484
0.6085	4000	13124
0.5700	4500	14765

Then, any one of a number of *Excel* functions can be used to interpolate
(Here we use *Excel*'s *Trendline* analysis)

p/p_{SL}	Altitude (ft)
0.707	9303
0.571	14640

Current altitude is approximately 9303 ft

The change in altitude is then 5337 ft

Alternatively, we can interpolate for each altitude by using a linear regression between adjacent data points

p/p_{SL}	Altitude (m)	Altitude (ft)
0.7372	2500	8203
0.6920	3000	9843

For

p/p_{SL}	Altitude (m)	Altitude (ft)
0.6085	4000	13124
0.5700	4500	14765

Then

0.7070	2834	9299
--------	------	------

0.5730	4461	14637
--------	------	-------

The change in altitude is then 5338 ft

Problem 3.4

[Difficulty: 2]

3.4 Your pressure gage indicates that the pressure in your cold tires is 0.25 MPa (gage) on a mountain at an elevation of 3500 m. What is the absolute pressure? After you drive down to sea level, your tires have warmed to 25°C. What pressure does your gage now indicate? Assume a U.S. Standard Atmosphere.

Given: Data on tire at 3500 m and at sea level

Find: Absolute pressure at 3500 m; pressure at sea level

Solution:

At an elevation of 3500 m, from Table

$$p_{SL} = 101 \cdot \text{kPa} \quad p_{atm} = 0.6492 \cdot p_{SL} \quad p_{atm} = 65.6 \cdot \text{kPa}$$

and we have

$$p_g = 0.25 \cdot \text{MPa} \quad p_g = 250 \cdot \text{kPa} \quad p = p_g + p_{atm} \quad p = 316 \cdot \text{kPa}$$

At sea level

$$p_{atm} = 101 \cdot \text{kPa}$$

Meanwhile, the tire has warmed up, from the ambient temperature at 3500 m, to 25°C.

At an elevation of 3500 m,

$$T_{cold} = 265.4 \cdot \text{K} \quad \text{and} \quad T_{hot} = (25 + 273) \cdot \text{K} \quad T_{hot} = 298 \text{ K}$$

Hence, assuming ideal gas behavior, $pV = mRT$, and that the tire is approximately a rigid container, the absolute pressure of the hot tire is

$$p_{hot} = \frac{T_{hot}}{T_{cold}} \cdot p \quad p_{hot} = 354 \cdot \text{kPa}$$

Then the gage pressure is

$$p_g = p_{hot} - p_{atm} \quad p_g = 253 \cdot \text{kPa}$$

Problem 3.5

[Difficulty: 2]

3.5 A 125-mL cube of solid oak is held submerged by a tether as shown. Calculate the actual force of the water on the bottom surface of the cube and the tension in the tether.

Given: Data on system

Find: Force on bottom of cube; tension in tether

Solution:

Basic equation $\frac{dp}{dy} = -\rho \cdot g$ or, for constant ρ $\Delta p = \rho \cdot g \cdot h$ where h is measured downwards

The absolute pressure at the interface is $p_{\text{interface}} = p_{\text{atm}} + SG_{\text{oil}} \cdot \rho \cdot g \cdot h_{\text{oil}}$

Then the pressure on the lower surface is $p_L = p_{\text{interface}} + \rho \cdot g \cdot h_L = p_{\text{atm}} + \rho \cdot g \cdot (SG_{\text{oil}} \cdot h_{\text{oil}} + h_L)$

For the cube $V = 125 \cdot \text{mL}$ $V = 1.25 \times 10^{-4} \cdot \text{m}^3$

Then the size of the cube is $d = V^{\frac{1}{3}}$ $d = 0.05 \text{ m}$ and the depth in water to the upper surface is $h_U = 0.3 \cdot \text{m}$

Hence $h_L = h_U + d$ $h_L = 0.35 \text{ m}$ where h_L is the depth in water to the lower surface

The force on the lower surface is $F_L = p_L \cdot A$ where $A = d^2$ $A = 0.0025 \text{ m}^2$

$$F_L = [p_{\text{atm}} + \rho \cdot g \cdot (SG_{\text{oil}} \cdot h_{\text{oil}} + h_L)] \cdot A$$

$$F_L = \left[101 \times 10^3 \cdot \frac{\text{N}}{\text{m}^2} + 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (0.8 \times 0.5 \cdot \text{m} + 0.35 \cdot \text{m}) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \right] \times 0.0025 \cdot \text{m}^2$$

$$F_L = 270.894 \text{ N}$$

Note: Extra decimals needed for computing T later!

For the tension in the tether, an FBD gives $\Sigma F_y = 0$ $F_L - F_U - W - T = 0$ or $T = F_L - F_U - W$

$$\text{where } F_U = [p_{\text{atm}} + \rho \cdot g \cdot (SG_{\text{oil}} \cdot h_{\text{oil}} + h_U)] \cdot A$$

Note that we could instead compute

$$\Delta F = F_L - F_U = \rho \cdot g \cdot SG_{oil} \cdot (h_L - h_U) \cdot A \quad \text{and} \quad T = \Delta F - W$$

Using F_U

$$F_U = \left[101 \times 10^3 \cdot \frac{\text{N}}{\text{m}^2} + 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (0.8 \times 0.5 \cdot \text{m} + 0.3 \cdot \text{m}) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \right] \times 0.0025 \cdot \text{m}^2$$

$$F_U = 269.668 \text{ N}$$

Note: Extra decimals needed for computing T later!

For the oak block

$$SG_{oak} = 0.77 \quad \text{so} \quad W = SG_{oak} \cdot \rho \cdot g \cdot V$$

$$W = 0.77 \times 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 1.25 \times 10^{-4} \cdot \text{m}^3 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad W = 0.944 \text{ N}$$

$$T = F_L - F_U - W \quad T = 0.282 \text{ N}$$

Problem 3.6

[Difficulty: 2]

3.6 The tube shown is filled with mercury at 20°C. Calculate the force applied to the piston.

Given: Data on system before and after applied force

Find: Applied force

Solution:

Basic equation $\frac{dp}{dy} = -\rho \cdot g$ or, for constant ρ $p = p_{atm} - \rho \cdot g \cdot (y - y_0)$ with $p(y_0) = p_{atm}$

For initial state $p_1 = p_{atm} + \rho \cdot g \cdot h$ and $F_1 = p_1 \cdot A = \rho \cdot g \cdot h \cdot A$ (Gage; F_1 is hydrostatic upwards force)

For the initial FBD $\Sigma F_y = 0$ $F_1 - W = 0$ $W = F_1 = \rho \cdot g \cdot h \cdot A$

For final state $p_2 = p_{atm} + \rho \cdot g \cdot H$ and $F_2 = p_2 \cdot A = \rho \cdot g \cdot H \cdot A$ (Gage; F_2 is hydrostatic upwards force)

For the final FBD $\Sigma F_y = 0$ $F_2 - W - F = 0$ $F = F_2 - W = \rho \cdot g \cdot H \cdot A - \rho \cdot g \cdot h \cdot A = \rho \cdot g \cdot A \cdot (H - h)$

$$F = \rho_{H_2O} \cdot SG \cdot g \cdot \frac{\pi \cdot D^2}{4} \cdot (H - h)$$

$$SG = 13.54$$

$$F = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 13.54 \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times \frac{\pi}{4} \times (0.05 \cdot \text{m})^2 \times (0.2 - 0.025) \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

$$F = 45.6 \text{ N}$$

Problem 3.7

(Difficulty: 1)

3.7 Calculate the absolute pressure and gage pressure in an open tank of crude oil 2.4 m below the liquid surface. If the tank is closed and pressurized to 130 kPa, what are the absolute pressure and gage pressure at this location.

Given: Location: $h = 2.4$ m below the liquid surface. Liquid: Crude oil.

Find: The absolute pressure p_a and gage pressure p_g for both open and closed tank .

Assumption: The gage pressure for the liquid surface is zero for open tank and closed tank. The oil is incompressible.

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

The density for the crude oil is:

$$\rho = 856 \frac{kg}{m^3}$$

The atmosphere pressure is:

$$p_{atmos} = 101000 Pa$$

The pressure for the closed tank is:

$$p_{tank} = 130 kPa = 130000 Pa$$

Using the hydrostatic relation, the gage pressure of open tank 2.4 m below the liquid surface is:

$$p_g = \rho gh = 856 \frac{kg}{m^3} \times 9.81 \frac{m}{s^2} \times 2.4 m = 20100 Pa$$

The absolute pressure of open tank at this location is:

$$p_a = p_g + p_{atmos} = 20100 Pa + 101000 Pa = 121100 Pa = 121.1 kPa$$

The gage pressure of closed tank at the same location below the liquid surface is the same as open tank:

$$p_g = \rho gh = 856 \frac{kg}{m^3} \times 9.81 \frac{m}{s^2} \times 2.4 m = 20100 Pa$$

The absolute pressure of closed tank at this location is:

$$p_a = p_g + p_{tank} = 20100 Pa + 130000 Pa = 150100 Pa = 150.1 kPa$$

Problem 3.8

(Difficulty: 1)

3.8 An open vessel contains carbon tetrachloride to a depth of 6 ft and water on the carbon tetrachloride to a depth of 5 ft . What is the pressure at the bottom of the vessel?

Given: Depth of carbon tetrachloride: $h_c = 6\text{ ft}$. Depth of water: $h_w = 5\text{ ft}$.

Find: The gage pressure p at the bottom of the vessel.

Assumption: The gage pressure for the liquid surface is zero. The fluid is incompressible.

Solution: Use the hydrostatic pressure relation to determine pressures in a fluid.

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

The density for the carbon tetrachloride is:

$$\rho_c = 1.59 \times 10^3 \frac{\text{kg}}{\text{m}^3} = 3.09 \frac{\text{slug}}{\text{ft}^3}$$

The density for the water is:

$$\rho_w = 1.0 \times 10^3 \frac{\text{kg}}{\text{m}^3} = 1.940 \frac{\text{slug}}{\text{ft}^3}$$

Using the hydrostatic relation, the gage pressure p at the bottom of the vessel is:

$$p = \rho_c g h_c + \rho_w g h_w$$

$$p = 3.09 \frac{\text{slug}}{\text{ft}^3} \times 32.2 \frac{\text{ft}}{\text{s}^2} \times 6\text{ ft} + 1.940 \frac{\text{slug}}{\text{ft}^3} \times 32.2 \frac{\text{ft}}{\text{s}^2} \times 5\text{ ft} = 909 \frac{\text{lbf}}{\text{ft}^2} = 6.25\text{ psi}$$

Problem 3.9

[Difficulty: 2]

3.9 A hollow metal cube with sides 100 mm floats at the interface between a layer of water and a layer of SAE 10W oil such that 10% of the cube is exposed to the oil. What is the pressure difference between the upper and lower horizontal surfaces? What is the average density of the cube?

Given: Properties of a cube floating at an interface

Find: The pressures difference between the upper and lower surfaces; average cube density

Solution:

The pressure difference is obtained from two applications of these equations:

$$p_U = p_0 + \rho_{\text{SAE10}} \cdot g \cdot (H - 0.1 \cdot d)$$

$$p_L = p_0 + \rho_{\text{SAE10}} \cdot g \cdot H + \rho_{\text{H}_2\text{O}} \cdot g \cdot 0.9 \cdot d$$

where p_U and p_L are the upper and lower pressures, p_0 is the oil free surface pressure, H is the depth of the interface, and d is the cube size

Hence the pressure difference is

$$\Delta p = p_L - p_U = \rho_{\text{H}_2\text{O}} \cdot g \cdot 0.9 \cdot d + \rho_{\text{SAE10}} \cdot g \cdot 0.1 \cdot d$$

$$\Delta p = \rho_{\text{H}_2\text{O}} \cdot g \cdot d \cdot (0.9 + SG_{\text{SAE10}} \cdot 0.1)$$

From Table $SG_{\text{SAE10}} = 0.92$

$$\Delta p = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 0.1 \cdot \text{m} \times (0.9 + 0.92 \times 0.1) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad \Delta p = 972 \text{ Pa}$$

For the cube density, set up a free body force balance for the cube

$$\Sigma F = 0 = \Delta p \cdot A - W$$

Hence

$$W = \Delta p \cdot A = \Delta p \cdot d^2$$

$$\rho_{\text{cube}} = \frac{m}{d^3} = \frac{W}{d^3 \cdot g} = \frac{\Delta p \cdot d^2}{d^3 \cdot g} = \frac{\Delta p}{d \cdot g}$$

$$\rho_{\text{cube}} = 972 \cdot \frac{\text{N}}{\text{m}^2} \times \frac{1}{0.1 \cdot \text{m}} \times \frac{\text{s}^2}{9.81 \cdot \text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2} \quad \rho_{\text{cube}} = 991 \frac{\text{kg}}{\text{m}^3}$$

Problem 3.10

[Difficulty: 2]

3.10 Compressed nitrogen (140 lbm) is stored in a spherical tank of diameter $D = 2.5$ ft at a temperature of 77°F . What is the pressure inside the tank? If the maximum allowable stress in the tank is 30 ksi, find the minimum theoretical wall thickness of the tank.

Given: Data on nitrogen tank

Find: Pressure of nitrogen; minimum required wall thickness

Assumption: Ideal gas behavior

Solution:

Ideal gas equation of state: $p \cdot V = M \cdot R \cdot T$

where, from Table A.6, for nitrogen $R = 55.16 \frac{\text{ft} \cdot \text{lbf}}{\text{lbm} \cdot \text{R}}$

Then the pressure of nitrogen is
$$p = \frac{M \cdot R \cdot T}{V} = M \cdot R \cdot T \left(\frac{6}{\pi \cdot D^3} \right)$$

$$p = 140 \cdot \text{lbm} \times 55.16 \frac{\text{ft} \cdot \text{lbf}}{\text{lbm} \cdot \text{R}} \times (77 + 460) \cdot \text{R} \times \left[\frac{6}{\pi \times (2.5 \cdot \text{ft})^3} \right] \times \left(\frac{\text{ft}}{12 \cdot \text{in}} \right)^2$$

$$p = 3520 \cdot \frac{\text{lbf}}{\text{in}^2}$$

To determine wall thickness, consider a free body diagram for one hemisphere:

$$\Sigma F = 0 = p \cdot \frac{\pi \cdot D^2}{4} - \sigma_c \cdot \pi \cdot D \cdot t$$

where σ_c is the circumferential stress in the container

Then
$$t = \frac{p \cdot \pi \cdot D^2}{4 \cdot \pi \cdot D \cdot \sigma_c} = \frac{p \cdot D}{4 \cdot \sigma_c}$$

$$t = 3520 \cdot \frac{\text{lbf}}{\text{in}^2} \times \frac{2.5 \cdot \text{ft}}{4} \times \frac{\text{in}^2}{30 \times 10^3 \cdot \text{lbf}}$$

$$t = 0.0733 \cdot \text{ft}$$

$$t = 0.880 \cdot \text{in}$$

Problem 3.11

(Difficulty: 2)

3.11 If at the surface of a liquid the specific weight is γ_0 , with z and p both zero, show that, if $E = \text{constant}$, the specific weight and pressure are given $\gamma = \frac{E}{\left(z + \frac{E}{\gamma_0}\right)}$ and $p = -E \ln \left(1 + \frac{\gamma_0 z}{E}\right)$.

Calculate specific weight and pressure at a depth of 2 km assuming $\gamma_0 = 10.0 \frac{kN}{m^3}$ and $E = 2070 \text{ MPa}$.

Given: Depth: $h = 2 \text{ km}$. The specific weight at surface of a liquid: $\gamma_0 = 10.0 \frac{kN}{m^3}$.

Find: The specific weight and pressure at a depth of 2 km.

Assumption: Bulk modulus is constant

Solution: Use the hydrostatic pressure relation and definition of bulk modulus to determine pressures in a fluid.

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

Definition of bulk modulus

$$E_v = \frac{dp}{d\rho/\rho} = \frac{dp}{d\gamma/\gamma}$$

Eliminating dp from the hydrostatic pressure relation and the bulk modulus definition:

$$dp = -\gamma dz = E_v \frac{d\gamma}{\gamma}$$

Or

$$dz = -E_v \frac{d\gamma}{\gamma^2}$$

Integrating for both sides we get:

$$z = E_v \frac{1}{\gamma} + c$$

At $z = 0$, $\gamma = \gamma_0$ so:

$$c = -E_v \frac{1}{\gamma_0}$$

$$z = E_v \frac{1}{\gamma} - E_v \frac{1}{\gamma_0}$$

Solving for γ , we have:

$$\gamma = \frac{E_v}{\left(z + \frac{E_v}{\gamma_0}\right)}$$

Solving for the pressure using the hydrostatic relation:

$$dp = -\gamma dz = -\frac{E_v}{\left(z + \frac{E_v}{\gamma_0}\right)} dz$$

Integrating both sides we to get:

$$p = -E_v \ln\left(z + \frac{E_v}{\gamma_0}\right) + c$$

At $z = 0$, $p = 0$ so:

$$c = E_v \ln\left(\frac{E_v}{\gamma_0}\right)$$

$$p = -E_v \ln\left(z + \frac{E_v}{\gamma_0}\right) + E_v \ln\left(\frac{E_v}{\gamma_0}\right) = -E_v \ln\left(1 + \frac{\gamma_0 z}{E_v}\right)$$

For the specific case

$$h = 2 \text{ km}$$

$$\gamma_0 = 10.0 \frac{kN}{m^3}$$

$$E_v = 2070 \text{ MPa}$$

The specific weight:

$$\gamma = \frac{E_v}{\left(z + \frac{E_v}{\gamma_0}\right)} = \frac{2070 \times 10^6 \text{ Pa}}{\left(-2000 \text{ Pa} + \frac{2070 \times 10^6 \text{ Pa}}{10 \times 10^3 \frac{N}{m^3}}\right)} = 10100 \frac{N}{m^3} = 10.1 \frac{kN}{m^3}$$

Pressure:

$$p = -E_v \ln\left(1 + \frac{\gamma_0 z}{E_v}\right) = -2070 \times 10^6 \text{ Pa} \times \ln\left(1 + 10000.0 \frac{kN}{m^3} \times \left(\frac{-2000 \text{ m}}{2070 \times 10^6 \text{ Pa}}\right)\right) = 20100 \text{ kPa}$$

Problem 3.12

(Difficulty: 2)

3.12 In the deep ocean the compressibility of seawater is significant in its effect on ρ and p . If $E = 2.07 \times 10^9 \text{ Pa}$, find the percentage change in the density and pressure at a depth of 10000 meters as compared to the values obtained at the same depth under the incompressible assumption. Let $\rho_0 = 1020 \frac{\text{kg}}{\text{m}^3}$ and the absolute pressure $p_0 = 101.3 \text{ kPa}$.

Given: Depth: $h = 10000 \text{ meters}$. The density: $\rho_0 = 1020 \frac{\text{kg}}{\text{m}^3}$. The absolute pressure: $p_0 = 101.3 \text{ kPa}$.

Find: The percent change in density $\rho\%$ and pressure $p\%$.

Assumption: The bulk modulus is constant

Solution: Use the relations developed in problem 3.11 for specific weight and pressure for a compressible liquid:

$$\gamma = \frac{E}{\left(z + \frac{E}{\gamma_0}\right)}$$
$$p = -E \ln \left(1 + \frac{\gamma_0 z}{E}\right)$$

The specific weight at sea level is:

$$\gamma_0 = \rho_0 g = 1020 \frac{\text{kg}}{\text{m}^3} \times 9.81 \frac{\text{m}}{\text{s}^2} = 10010 \frac{\text{N}}{\text{m}^3}$$

The specific weight and density at 10000 m depth are

$$\gamma = \frac{E}{\left(z + \frac{E}{\gamma_0}\right)} = \frac{2.07 \times 10^9}{\left(-10000 + \frac{2.07 \times 10^9}{10010}\right)} \frac{\text{N}}{\text{m}^3} = 10520 \frac{\text{N}}{\text{m}^3}$$
$$\rho = \frac{\gamma}{g} = \frac{10520}{9.81} \frac{\text{kg}}{\text{m}^3} = 1072 \frac{\text{kg}}{\text{m}^3}$$

The percentage change in density is

$$\rho\% = \frac{\rho - \rho_0}{\rho_0} = \frac{1072 - 1020}{1020} = 5.1 \%$$

The gage pressure at a depth of 10000m is:

$$p = -E \ln \left(1 + \frac{\gamma_0 z}{E}\right) = 101.3 \text{ kPa} - 2.07 \times 10^9 \times \ln \left(1 + \frac{10010 \times (-10000)}{2.07 \times 10^9}\right) \text{ Pa} = 102600 \text{ kPa}$$

The pressure assuming that the water is incompressible is:

$$p_{in} = \rho gh = 1020 \frac{kg}{m^3} \times 9.81 \frac{m}{s^2} \times 10000 m = 100062 kPa$$

The percent difference in pressure is:

$$p\% = \frac{p - p_0}{p_0} = \frac{102600 kPa - 100062 kPa}{100062 kPa} = 2.54 \%$$

Problem 3.13

[Difficulty: 4]

3.13 Assuming the bulk modulus is constant for seawater, derive an expression for the density variation with depth, h , below the surface. Show that the result may be written

$$\rho \approx \rho_0 + bh$$

where ρ_0 is the density at the surface. Evaluate the constant b . Then, using the approximation, obtain an equation for the variation of pressure with depth below the surface. Determine the depth in feet at which the error in pressure predicted by the approximate solution is 0.01 percent.

Given: Model behavior of seawater by assuming constant bulk modulus

Find:

- (a) Expression for density as a function of depth h .
- (b) Show that result may be written as $\rho = \rho_0 + bh$
- (c) Evaluate the constant b
- (d) Use results of (b) to obtain equation for $p(h)$
- (e) Determine depth at which error in predicted pressure is 0.01%

Solution: From Table A.2, App. A: $SG_O = 1.025$ $E_v = 2.42 \cdot \text{GPa} = 3.51 \times 10^5 \cdot \text{psi}$

Governing Equations: $\frac{dp}{dh} = \rho \cdot g$ (Hydrostatic Pressure - h is positive downwards)

$$E_v = \frac{dp}{\frac{d\rho}{\rho}} \quad (\text{Definition of Bulk Modulus})$$

Then $dp = \rho \cdot g \cdot dh = E_v \cdot \frac{d\rho}{\rho}$ or $\frac{d\rho}{\rho^2} = \frac{g}{E_v} dh$ Now if we integrate: $\int_{\rho_0}^{\rho} \frac{1}{\rho^2} d\rho = \int_0^h \frac{g}{E_v} dh$

After integrating: $\frac{\rho - \rho_0}{\rho \cdot \rho_0} = \frac{g \cdot h}{E_v}$ Therefore: $\rho = \frac{E_v \cdot \rho_0}{E_v - g \cdot h \cdot \rho_0}$ and $\frac{\rho}{\rho_0} = \frac{1}{1 - \frac{\rho_0 \cdot g \cdot h}{E_v}}$

Now for $\frac{\rho_0 \cdot g \cdot h}{E_v} \ll 1$, the binomial expansion may be used to approximate the density: $\frac{\rho}{\rho_0} = 1 + \frac{\rho_0 \cdot g \cdot h}{E_v}$ (Binomial expansion may be found in a host of sources, e.g. *CRC Handbook of Mathematics*)

In other words, $\rho = \rho_0 + b \cdot h$ where $b = \frac{\rho_0^2 \cdot g}{E_v}$

Since $dp = \rho \cdot g \cdot dh$ then an approximate expression for the pressure as a function of depth is:

$$p_{\text{approx}} - p_{\text{atm}} = \int_0^h (\rho_0 + b \cdot h) \cdot g \, dh \rightarrow p_{\text{approx}} - p_{\text{atm}} = \frac{g \cdot h \cdot (2 \cdot \rho_0 + b \cdot h)}{2}$$

Solving for p_{approx} we get:

$$p_{\text{approx}} = p_{\text{atm}} + \frac{g \cdot h \cdot (2 \cdot \rho_o + b \cdot h)}{2} = p_{\text{atm}} + \rho_o \cdot g \cdot h + \frac{b \cdot g \cdot h^2}{2} = p_{\text{atm}} + \left(\rho_o \cdot h + \frac{b \cdot h^2}{2} \right) \cdot g$$

Now if we substitute in the expression for b and simplify, we get:

$$p_{\text{approx}} = p_{\text{atm}} + \left(\rho_o \cdot h + \frac{\rho_o^2 \cdot g \cdot h^2}{E_v} \cdot \frac{1}{2} \right) \cdot g = p_{\text{atm}} + \rho_o \cdot g \cdot h \cdot \left(1 + \frac{\rho_o \cdot g \cdot h}{2 \cdot E_v} \right) \quad p_{\text{approx}} = p_{\text{atm}} + \rho_o \cdot g \cdot h \cdot \left(1 + \frac{\rho_o \cdot g \cdot h}{2 E_v} \right)$$

The exact solution for p(h) is obtained by utilizing the exact solution for ρ(h). Thus:

$$p_{\text{exact}} - p_{\text{atm}} = \int_{\rho_o}^{\rho} \frac{E_v}{\rho} d\rho = E_v \cdot \ln\left(\frac{\rho}{\rho_o}\right) \quad \text{Substituting for } \frac{\rho}{\rho_o} \text{ we get:} \quad p_{\text{exact}} = p_{\text{atm}} + E_v \cdot \ln\left(1 - \frac{\rho_o \cdot g \cdot h}{E_v}\right)^{-1}$$

$$\text{If we let } x = \frac{\rho_o \cdot g \cdot h}{E_v} \quad \text{For the error to be 0.01\%:} \quad \frac{\Delta p_{\text{exact}} - \Delta p_{\text{approx}}}{\Delta p_{\text{exact}}} = 1 - \frac{\rho_o \cdot g \cdot h \cdot \left(1 + \frac{x}{2}\right)}{E_v \cdot \ln[(1-x)^{-1}]} = 1 - \frac{x \cdot \left(1 + \frac{x}{2}\right)}{\ln[(1-x)^{-1}]} = 0.0001$$

This equation requires an iterative solution, e.g. Excel's Goal Seek. The result is: $x = 0.01728$ Solving x for h:

$$h = \frac{x \cdot E_v}{\rho_o \cdot g} \quad h = 0.01728 \times 3.51 \times 10^5 \cdot \frac{\text{lb} \cdot \text{f}}{\text{in}^2} \times \frac{\text{ft}^3}{1.025 \times 1.94 \cdot \text{slug}} \times \frac{\text{s}^2}{32.2 \cdot \text{ft}} \times \left(\frac{12 \cdot \text{in}}{\text{ft}}\right)^2 \times \frac{\text{slug} \cdot \text{ft}}{\text{lb} \cdot \text{f} \cdot \text{s}^2} \quad h = 1.364 \times 10^4 \cdot \text{ft}$$

This depth is over 2.5 miles, so the incompressible fluid approximation is a reasonable one at all but the lowest depths of the ocean.

Problem 3.14

[Difficulty: 3]

3.14 An inverted cylindrical container is lowered slowly beneath the surface of a pool of water. Air trapped in the container is compressed isothermally as the hydrostatic pressure increases. Develop an expression for the water height, y , inside the container in terms of the container height, H , and depth of submersion, h . Plot y/H versus h/H .

Given: Cylindrical cup lowered slowly beneath pool surface

Find: Expression for y in terms of h and H .
Plot y/H vs. h/H .

Solution:

Governing Equations: $\frac{dp}{dh} = \rho \cdot g$ (Hydrostatic Pressure - h is positive downwards)

$$p \cdot V = M \cdot R \cdot T \quad \text{(Ideal Gas Equation)}$$

Assumptions:

- (1) Constant temperature compression of air inside cup
- (2) Static liquid
- (3) Incompressible liquid

First we apply the ideal gas equation (at constant temperature) for the pressure of the air in the cup: $p \cdot V = \text{constant}$

Therefore: $p \cdot V = p_a \cdot \frac{\pi}{4} \cdot D^2 \cdot H = p \cdot \frac{\pi}{4} \cdot D^2 \cdot (H - y)$ and upon simplification: $p_a \cdot H = p \cdot (H - y)$

Now we look at the hydrostatic pressure equation for the pressure exerted by the water. Since ρ is constant, we integrate:

$$p - p_a = \rho \cdot g \cdot (h - y) \quad \text{at the water-air interface in the cup.}$$

Since the cup is submerged to a depth of h , these pressures must be equal:

$$p_a \cdot H = [p_a + \rho \cdot g \cdot (h - y)] \cdot (H - y) = p_a \cdot H - p_a \cdot y + \rho \cdot g \cdot (h - y) \cdot (H - y)$$

Expanding out the right hand side of this expression:

$$0 = -p_a \cdot y + \rho \cdot g \cdot (h - y) \cdot (H - y) = \rho \cdot g \cdot h \cdot H - \rho \cdot g \cdot h \cdot y - \rho \cdot g \cdot H \cdot y + \rho \cdot g \cdot y^2 - p_a \cdot y$$

$$\rho \cdot g \cdot y^2 - \left[p_a + \rho \cdot g \cdot (h + H) \right] \cdot y + \rho \cdot g \cdot h \cdot H = 0 \quad y^2 - \left[\frac{p_a}{\rho \cdot g} + (h + H) \right] \cdot y + h \cdot H = 0$$

We now use the quadratic equation: $y = \frac{\left[\frac{p_a}{\rho \cdot g} + (h + H) \right] \pm \sqrt{\left[\frac{p_a}{\rho \cdot g} + (h + H) \right]^2 - 4 \cdot h \cdot H}}{2}$

we only use the minus sign because y can never be larger than H .

Now if we divide both sides by H, we get an expression for y/H:

$$\frac{y}{H} = \frac{\left(\frac{p_a}{\rho \cdot g \cdot H} + \frac{h}{H} + 1\right) - \sqrt{\left(\frac{p_a}{\rho \cdot g \cdot H} + \frac{h}{H} + 1\right)^2 - 4 \cdot \frac{h}{H}}}{2}$$

The exact shape of this curve will depend upon the height of the cup. The plot below was generated assuming:

$$p_a = 101.3 \cdot \text{kPa}$$

$$H = 1 \cdot \text{m}$$

Problem 3.15

[Difficulty: 2]

3.15 A water tank filled with water to a depth of 16 ft has in inspection cover (1 in. \times 1 in.) at its base, held in place by a plastic bracket. The bracket can hold a load of 9 lbf. Is the bracket strong enough? If it is, what would the water depth have to be to cause the bracket to break?

Given: Data on water tank and inspection cover

Find: If the support bracket is strong enough; at what water depth would it fail

Assumptions: Water is incompressible and static

Solution:

Basic equation $\frac{dp}{dy} = -\rho \cdot g$ or, for constant ρ $\Delta p = \rho \cdot g \cdot h$ where h is measured downwards

The absolute pressure at the base is $p_{base} = p_{atm} + \rho \cdot g \cdot h$ where $h = 16 \cdot \text{ft}$

The gage pressure at the base is $p_{base} = \rho \cdot g \cdot h$ This is the pressure to use as we have p_{atm} on the outside of the cover.

The force on the inspection cover is $F = p_{base} \cdot A$ where $A = 1 \cdot \text{in} \times 1 \cdot \text{in}$ $A = 1 \cdot \text{in}^2$

$$F = \rho \cdot g \cdot h \cdot A$$

$$F = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 16 \cdot \text{ft} \times 1 \cdot \text{in}^2 \times \left(\frac{\text{ft}}{12 \cdot \text{in}} \right)^2 \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}}$$

$F = 6.94 \cdot \text{lbf}$ The bracket is strong enough (it can take 9 lbf).

To find the maximum depth we start with $F = 9.00 \cdot \text{lbf}$

$$h = \frac{F}{\rho \cdot g \cdot A}$$

$$h = 9 \cdot \text{lbf} \times \frac{1}{1.94 \cdot \text{slug}} \times \frac{\text{ft}^3}{32.2 \cdot \frac{\text{s}^2}{\text{ft}}} \times \frac{1}{\text{in}^2} \times \left(\frac{12 \cdot \text{in}}{\text{ft}} \right)^2 \times \frac{\text{slug} \cdot \text{ft}}{\text{lbf} \cdot \text{s}^2}$$

$$h = 20.7 \cdot \text{ft}$$

Problem 3.16

[Difficulty: 2]

3.16 A partitioned tank as shown contains water and mercury. What is the gage pressure in the air trapped in the left chamber? What pressure would the air on the left need to be pumped to in order to bring the water and mercury free surfaces level?

Given: Data on partitioned tank

Find: Gage pressure of trapped air; pressure to make water and mercury levels equal

Solution:

The pressure difference is obtained from repeated application of Eq. 3.7, or in other words, from Eq. 3.8. Starting from the right air chamber

$$p_{\text{gage}} = SG_{\text{Hg}} \times \rho_{\text{H}_2\text{O}} \times g \times (3 \cdot \text{m} - 2.9 \cdot \text{m}) - \rho_{\text{H}_2\text{O}} \times g \times 1 \cdot \text{m}$$

$$p_{\text{gage}} = \rho_{\text{H}_2\text{O}} \times g \times (SG_{\text{Hg}} \times 0.1 \cdot \text{m} - 1.0 \cdot \text{m})$$

$$p_{\text{gage}} = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (13.55 \times 0.1 \cdot \text{m} - 1.0 \cdot \text{m}) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad p_{\text{gage}} = 3.48 \cdot \text{kPa}$$

If the left air pressure is now increased until the water and mercury levels are now equal, Eq. 3.8 leads to

$$p_{\text{gage}} = SG_{\text{Hg}} \times \rho_{\text{H}_2\text{O}} \times g \times 1.0 \cdot \text{m} - \rho_{\text{H}_2\text{O}} \times g \times 1.0 \cdot \text{m}$$

$$p_{\text{gage}} = \rho_{\text{H}_2\text{O}} \times g \times (SG_{\text{Hg}} \times 1 \cdot \text{m} - 1.0 \cdot \text{m})$$

$$p_{\text{gage}} = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (13.55 \times 1 \cdot \text{m} - 1.0 \cdot \text{m}) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad p_{\text{gage}} = 123 \cdot \text{kPa}$$

Problem 3.17

[Difficulty: 2]

3.17 Consider the two-fluid manometer shown. Calculate the applied pressure difference.

Given: Two-fluid manometer as shown

$$l = 10.2 \cdot \text{mm} \quad SG_{\text{ct}} = 1.595$$

Find: Pressure difference

Solution: We will apply the hydrostatics equation.

Governing equations:

$$\frac{dp}{dh} = \rho \cdot g$$

(Hydrostatic Pressure - h is positive downwards)

$$\rho = SG \cdot \rho_{\text{water}}$$

(Definition of Specific Gravity)

Assumptions:

- (1) Static liquid
- (2) Incompressible liquid

Starting at point 1 and progressing to point 2 we have:

$$p_1 + \rho_{\text{water}} \cdot g \cdot (d + l) - \rho_{\text{ct}} \cdot g \cdot l - \rho_{\text{water}} \cdot g \cdot d = p_2$$

Simplifying and solving for $p_2 - p_1$ we have:

$$\Delta p = p_2 - p_1 = \rho_{\text{ct}} \cdot g \cdot l - \rho_{\text{water}} \cdot g \cdot l = (SG_{\text{ct}} - 1) \cdot \rho_{\text{water}} \cdot g \cdot l$$

Substituting the known data:

$$\Delta p = (1.591 - 1) \times 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 10.2 \cdot \text{mm} \times \frac{\text{m}}{10^3 \cdot \text{mm}} \quad \Delta p = 59.1 \text{ Pa}$$

Problem 3.18

[Difficulty: 2]

3.18

The manometer shown contains water and kerosene. With both tubes open to the atmosphere, the free-surface elevations differ by $H_0 = 20.0$ mm. Determine the elevation difference when a pressure of 98.0 Pa (gage) is applied to the right tube.

Given: Two fluid manometer contains water and kerosene. With both tubes open to atmosphere, the difference in free surface elevations is known

$$H_0 = 20\text{-mm} \quad SG_k = 0.82$$

Find: The elevation difference, H , between the free surfaces of the fluids when a gage pressure of 98.0 Pa is applied to the right tube.

Solution: We will apply the hydrostatics equation.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g$$

(Hydrostatic Pressure - h is positive downwards)

$$\rho = SG \cdot \rho_{\text{water}}$$

(Definition of Specific Gravity)

Assumptions: (1) Static liquid
(2) Incompressible liquid

When the gage pressure Δp is applied to the right tube, the water in the right tube is displaced downward by a distance, l . The kerosene in the left tube is displaced upward by the same distance, l .

Under the applied gage pressure Δp , the elevation difference, H , is:

$$H = H_0 + 2 \cdot l$$

Since points A and B are at the same elevation in the same fluid, their pressures are the same. Initially:

$$p_A = \rho_k \cdot g \cdot (H_0 + H_1) \quad p_B = \rho_{\text{water}} \cdot g \cdot H_1$$

Setting these pressures equal:

$$\rho_k \cdot g \cdot (H_0 + H_1) = \rho_{\text{water}} \cdot g \cdot H_1$$

Solving for H_1

$$H_1 = \frac{\rho_k \cdot H_0}{\rho_{\text{water}} - \rho_k} = \frac{SG_k \cdot H_0}{1 - SG_k} \quad H_1 = \frac{0.82 \times 20\text{-mm}}{1 - 0.82} \quad H_1 = 91.11\text{-mm}$$

Now under the applied gage pressure:

$$p_A = \rho_k \cdot g \cdot (H_0 + H_1) + \rho_{\text{water}} \cdot g \cdot l \quad p_B = \Delta p + \rho_{\text{water}} \cdot g \cdot (H_1 - l)$$

Setting these pressures equal:

$$SG_k \cdot (H_o + H_l) + l = \frac{\Delta p}{\rho_{\text{water}} \cdot g} + (H_l - l) \quad l = \frac{1}{2} \left[\frac{\Delta p}{\rho_{\text{water}} \cdot g} + H_l - SG_k \cdot (H_o + H_l) \right]$$

Substituting in known values we get:

$$l = \frac{1}{2} \times \left[98.0 \cdot \frac{\text{N}}{\text{m}^2} \times \frac{1}{999} \frac{\text{m}^3}{\text{kg}} \times \frac{1}{9.81} \cdot \frac{\text{s}^2}{\text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2} + [91.11 \cdot \text{mm} - 0.82 \times (20 \cdot \text{mm} + 91.11 \cdot \text{mm})] \times \frac{\text{m}}{10^3 \cdot \text{mm}} \right] \quad l = 5.000 \cdot \text{mm}$$

Now we solve for H:

$$H = 20 \cdot \text{mm} + 2 \times 5.000 \cdot \text{mm}$$

$$H = 30.0 \cdot \text{mm}$$

Problem 3.19

[Difficulty: 2]

3.19

Determine the gage pressure in kPa at point *a*, if liquid *A* has SG = 1.20 and liquid *B* has SG = 0.75. The liquid surrounding point *a* is water, and the tank on the left is open to the atmosphere.

Given: Data on manometer

Find: Gage pressure at point *a*

Assumption: Water, liquids A and B are static and incompressible

Solution:

Basic equation $\frac{dp}{dy} = -\rho \cdot g$ or, for constant ρ $\Delta p = \rho \cdot g \cdot \Delta h$

where Δh is height difference

Starting at point *a* $p_1 = p_a - \rho_{H_2O} \cdot g \cdot h_1$ where $h_1 = 0.125 \cdot m + 0.25 \cdot m$ $h_1 = 0.375 \cdot m$

Next, in liquid *A* $p_2 = p_1 + SG_A \cdot \rho_{H_2O} \cdot g \cdot h_2$ where $h_2 = 0.25 \cdot m$

Finally, in liquid *B* $p_{atm} = p_2 - SG_B \cdot \rho_{H_2O} \cdot g \cdot h_3$ where $h_3 = 0.9 \cdot m - 0.4 \cdot m$ $h_3 = 0.5 \cdot m$

Combining the three equations

$$p_{atm} = (p_1 + SG_A \cdot \rho_{H_2O} \cdot g \cdot h_2) - SG_B \cdot \rho_{H_2O} \cdot g \cdot h_3 = p_a - \rho_{H_2O} \cdot g \cdot h_1 + SG_A \cdot \rho_{H_2O} \cdot g \cdot h_2 - SG_B \cdot \rho_{H_2O} \cdot g \cdot h_3$$

$$p_a = p_{atm} + \rho_{H_2O} \cdot g \cdot (h_1 - SG_A \cdot h_2 + SG_B \cdot h_3)$$

or in gage pressures $p_a = \rho_{H_2O} \cdot g \cdot (h_1 - SG_A \cdot h_2 + SG_B \cdot h_3)$

$$p_a = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times [0.375 - (1.20 \times 0.25) + (0.75 \times 0.5)] \cdot m \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

$$p_a = 4.41 \times 10^3 \text{ Pa} \quad p_a = 4.41 \cdot \text{kPa} \quad (\text{gage})$$

Problem 3.20

(Difficulty: 1)

3.20 With the manometer reading as shown, calculate p_x .

Given: Oil specific gravity: $SG_{oil} = 0.85$ Depth: $h_1 = 60 \text{ inch}$. $h_2 = 30 \text{ inch}$.

Find: The pressure p_x .

Assumption: Fluids are incompressible

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

Integrating with respect to z for an incompressible fluid, we have the relation for the pressure difference over a difference in elevation (h):

$$\Delta p = \rho gh$$

Repeated application of this relation yields

$$p_x = SG_{oil}\gamma_{water}h_1 + \gamma_M h_2$$

The specific weight for mercury is:

$$\gamma_M = 845 \frac{\text{lbf}}{\text{ft}^3}$$

The pressure at the desired location is

$$p_x = 0.85 \times 62.4 \frac{\text{lbf}}{\text{ft}^3} \times \left(\frac{60}{12}\right) \text{ ft} + 845 \frac{\text{lbf}}{\text{ft}^3} \times \left(\frac{30}{12}\right) \text{ ft} = 2380 \frac{\text{lbf}}{\text{ft}^2} = 16.5 \text{ psi}$$

Problem 3.21

(Difficulty: 2)

3.21 Calculate $p_x - p_y$ for this inverted U-tube manometer.

Given: Oil specific gravity: $SG_{oil} = 0.90$ Depth: $h_1 = 65 \text{ inch}$. $h_2 = 20 \text{ inch}$. $h_3 = 10 \text{ inch}$.

Find: The pressure difference $p_x - p_y$.

Assume: The fluids are incompressible

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

Integrating with respect to z for an incompressible fluid, we have the relation for the pressure difference over a difference in elevation (h):

$$\Delta p = \rho gh$$

Starting at the location of the unknown pressure p_x , we have the following relations for the hydrostatic pressure:

$$p_x - p_1 = \gamma_{water} h_1$$

$$p_1 - p_2 = -SG_{oil} \gamma_{water} h_3$$

$$p_2 - p_y = -\gamma_{water} (h_1 - h_2 - h_3)$$

Adding these three equations together

$$p_x - p_y = \gamma_{water} (h_2 + h_3) - SG_{oil} \gamma_{water} h_3$$

The pressure difference is then

$$p_x - p_y = 62.4 \frac{lbf}{ft^3} \times \frac{(10 + 20)}{12} ft - 0.9 \times 62.4 \frac{lbf}{ft^3} \times \frac{10}{12} ft = 109.2 \frac{lbf}{ft^2} = 0.758 \text{ psi}$$

Problem 3.22

(Difficulty: 2)

3.22 An inclined gage having a tube of 3 mm bore, laid on a slope of 1:20, and a reservoir of 25 mm diameter contains silicon oil (SG 0.84). What distance will the oil move along the tube when a pressure of 25 mm of water is connected to the gage?

Given: Silicon oil specific gravity: $SG_{oil} = 0.84$. Diameter: $D_1 = 3 \text{ mm}$. $D_2 = 25 \text{ mm}$.

Depth: $h_{water} = 25 \text{ mm}$. Slope angle: 1:20.

Find: The distance x of the oil move along the tube.

Assumption: Fluids are incompressible

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

Integrating with respect to z for an incompressible fluid, we have the relation for the pressure difference over a difference in elevation (h):

$$\Delta p = \rho g h$$

We have the volume of the oil as constant, so:

$$A_{reservoir} \Delta h = A_{tube} x$$

or

$$\frac{\Delta h}{x} = \frac{A_{tube}}{A_{reservoir}} = \frac{D_1^2}{D_2^2} = \frac{9}{625}$$

When a pressure of 25 mm of water is connected with the gage we have:

$$\gamma_{water} h_{water} = SG_{oil} \gamma_{water} h$$

$$h = \frac{h_{water}}{SG_{oil}} = 29.8 \text{ mm}$$

Using these relations, we obtain, accounting for the slope of the manometer:

$$h = \Delta h + \frac{x}{\sqrt{20^2 + 1^2}} = \left(\frac{9}{625} + \frac{1}{\sqrt{20^2 + 1^2}} \right) x$$

$$h = \Delta h + \frac{x}{\sqrt{401}} = \left(\frac{9}{625} + \frac{1}{\sqrt{401}} \right) x$$

$$x = \frac{h}{\left(\frac{9}{625} + \frac{1}{\sqrt{401}} \right)} = 463 \text{ mm}$$

Problem 3.23

[Difficulty: 2]

3.23 Water flows downward along a pipe that is inclined at 30° below the horizontal, as shown. Pressure difference $p_A - p_B$ is due partly to gravity and partly to friction. Derive an algebraic expression for the pressure difference. Evaluate the pressure difference if $L = 5$ ft and $h = 6$ in.

Given: Water flow in an inclined pipe as shown. The pressure difference is measured with a two-fluid manometer

$$L = 5 \text{ ft} \quad h = 6 \text{ in} \quad SG_{\text{Hg}} = 13.55$$

Find: Pressure difference between A and B

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad \text{(Hydrostatic Pressure - h is positive downwards)}$$

$$\rho = SG \cdot \rho_{\text{water}} \quad \text{(Definition of Specific Gravity)}$$

Assumptions:

- (1) Static liquid
- (2) Incompressible liquid
- (3) Gravity is constant

Integrating the hydrostatic pressure equation we get:

$$\Delta p = \rho \cdot g \cdot \Delta h$$

Progressing through the manometer from A to B:

$$p_A + \rho_{\text{water}} \cdot g \cdot L \cdot \sin(30^\circ) + \rho_{\text{water}} \cdot g \cdot a + \rho_{\text{water}} \cdot g \cdot h - \rho_{\text{Hg}} \cdot g \cdot h - \rho_{\text{water}} \cdot g \cdot a = p_B$$

Simplifying terms and solving for the pressure difference:

$$\Delta p = p_A - p_B = \rho_{\text{water}} \cdot g \cdot \left[h \cdot (SG_{\text{Hg}} - 1) - L \cdot \sin(30^\circ) \right]$$

Substituting in values:

$$\Delta p = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \frac{\text{ft}}{\text{s}^2} \times \left[6 \text{ in} \times \frac{\text{ft}}{12 \text{ in}} \times (13.55 - 1) - 5 \text{ ft} \times \sin(30^\circ) \right] \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}} \times \left(\frac{\text{ft}}{12 \text{ in}} \right)^2 \quad \Delta p = 1.638 \text{ psi}$$

Problem 3.24

[Difficulty: 2]

3.24 A reservoir manometer has vertical tubes of diameter $D = 18 \text{ mm}$ and $d = 6 \text{ mm}$. The manometer liquid is Meriam red oil. Develop an algebraic expression for liquid deflection L in the small tube when gage pressure Δp is applied to the reservoir. Evaluate the liquid deflection when the applied pressure is equivalent to 25 mm of water (gage).

Given: Reservoir manometer with vertical tubes of known diameter. Gage liquid is Meriam red oil

$$D = 18 \text{ mm} \quad d = 6 \text{ mm}$$

$$SG_{\text{oil}} = 0.827$$

Find: The manometer deflection, L when a gage pressure equal to 25 mm of water is applied to the reservoir.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards})$$

$$\rho = SG \cdot \rho_{\text{water}} \quad (\text{Definition of Specific Gravity})$$

Assumptions:

- (1) Static liquid
- (2) Incompressible liquid

Integrating the hydrostatic pressure equation we get:

$$\Delta p = \rho \cdot g \cdot \Delta h$$

Beginning at the free surface of the reservoir, and accounting for the changes in pressure with elevation:

$$p_{\text{atm}} + \Delta p + \rho_{\text{oil}} \cdot g \cdot (x + L) = p_{\text{atm}}$$

Upon simplification: $x + L = \frac{\Delta p}{\rho_{\text{oil}} \cdot g}$ The gage pressure is defined as: $\Delta p = \rho_{\text{water}} \cdot g \cdot \Delta h$ where $\Delta h = 25 \text{ mm}$

Combining these two expressions: $x + L = \frac{\rho_{\text{water}} \cdot g \cdot h}{\rho_{\text{oil}} \cdot g} = \frac{\Delta h}{SG_{\text{oil}}}$

x and L are related through the manometer dimensions: $\frac{\pi}{4} \cdot D^2 \cdot x = \frac{\pi}{4} \cdot d^2 \cdot L \quad x = \left(\frac{d}{D}\right)^2 L$

Therefore: $L = \frac{\Delta h}{SG_{\text{oil}} \cdot \left[1 + \left(\frac{d}{D}\right)^2\right]}$ Substituting values into the expression: $L = \frac{25 \text{ mm}}{0.827 \cdot \left[1 + \left(\frac{6 \text{ mm}}{18 \text{ mm}}\right)^2\right]}$

(Note: $s = \frac{L}{\Delta h}$ which yields $s = 1.088$ for this manometer.) $L = 27.2 \text{ mm}$

Problem 3.25

[Difficulty: 2]

3.25 A rectangular tank, open to the atmosphere, is filled with water to a depth of 2.5 m as shown. A U-tube manometer is connected to the tank at a location 0.7 m above the tank bottom. If the zero level of the Meriam blue manometer fluid is 0.2 m below the connection, determine the deflection l after the manometer is connected and all air has been removed from the connecting leg.

Given: A U-tube manometer is connected to the open tank filled with water as shown (manometer fluid is Meriam blue)

$$D_1 = 2.5 \cdot \text{m} \quad D_2 = 0.7 \cdot \text{m} \quad d = 0.2 \cdot \text{m} \quad SG_{\text{oil}} = 1.75$$

Find: The manometer deflection, l

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g$$

(Hydrostatic Pressure - h is positive downwards)

$$\rho = SG \cdot \rho_{\text{water}}$$

(Definition of Specific Gravity)

Assumptions:

- (1) Static liquid
- (2) Incompressible liquid

Integrating the hydrostatic pressure equation we get:

$$\Delta p = \rho \cdot g \cdot \Delta h$$

When the tank is filled with water, the oil in the left leg of the manometer is displaced downward by $l/2$. The oil in the right leg is displaced upward by the same distance, $l/2$.

Beginning at the free surface of the tank, and accounting for the changes in pressure with elevation:

$$P_{\text{atm}} + \rho_{\text{water}} \cdot g \cdot \left(D_1 - D_2 + d + \frac{l}{2} \right) - \rho_{\text{oil}} \cdot g \cdot l = P_{\text{atm}}$$

Upon simplification:

$$\rho_{\text{water}} \cdot g \cdot \left(D_1 - D_2 + d + \frac{l}{2} \right) = \rho_{\text{oil}} \cdot g \cdot l$$

$$D_1 - D_2 + d + \frac{l}{2} = SG_{\text{oil}} \cdot l$$

$$l = \frac{D_1 - D_2 + d}{SG_{\text{oil}} - \frac{1}{2}}$$

$$l = \frac{2.5 \cdot \text{m} - 0.7 \cdot \text{m} + 0.2 \cdot \text{m}}{1.75 - \frac{1}{2}}$$

$$l = 1.600 \text{ m}$$

Problem 3.26

(Difficulty: 2)

3.26 The sketch shows a sectional view through a submarine. Calculate the depth of submarine, y . Assume the specific weight of the seawater is $10.0 \frac{kN}{m^3}$.

Given: Atmos. Pressure: $p_{atmos} = 740 \text{ mm Hg}$. Seawater specific weight: $\gamma = 10.0 \frac{kN}{m^3}$. All the dimensional relationship is shown in the figure.

Find: The depth y .

Assumption: Fluids are incompressible

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

Integrating with respect to z for an incompressible fluid, we have the relation for the pressure difference over a difference in elevation (h):

$$\Delta p = \rho gh$$

Using the barometer reading with 760 mm as atmospheric pressure, the pressure inside the submarine is:

$$p = \frac{840 \text{ mm}}{760 \text{ mm}} \times 101.3 \times 10^3 \text{ Pa} = 111.6 \times 10^3 \text{ Pa}$$

However, the actual atmosphere pressure is:

$$p_{atmos} = \frac{740 \text{ mm}}{760 \text{ mm}} \times 101.3 \times 10^3 \text{ Pa} = 98.3 \times 10^3 \text{ Pa}$$

For the manometer, using the hydrostatic relation, we have for the pressure, where y is the depth of the submarine:

$$p = p_{atmos} + \gamma y + \gamma \times 200 \text{ mm} - \gamma_{Hg} \times 400 \text{ mm}$$
$$y = \frac{p + \gamma_{Hg} \times 400 \text{ mm} - \gamma \times 200 \text{ mm} - p_{atmos}}{\gamma}$$

The specific weight for mercury is:

$$\gamma_{Hg} = 133.1 \frac{\text{kN}}{\text{m}^3}$$

So we have for the depth y :

$$y = \frac{111.6 \times 10^3 \text{ Pa} + 133.1 \times 1000 \frac{\text{N}}{\text{m}^3} \times 0.4 \text{ m} - 1000 \frac{\text{N}}{\text{m}^3} \times 0.2 \text{ m} - 98.3 \times 10^3 \text{ Pa}}{1000 \frac{\text{N}}{\text{m}^3}}$$
$$y = 6.45 \text{ m}$$

Problem 3.27

(Difficulty: 1)

3.27 The manometer reading is 6 in. when the tank is empty (water surface at A). Calculate the manometer reading when the cone is filled with water.

Find: The manometer reading when the tank is filled with water.

Assumption: Fluids are static and incompressible

Solution: Use the hydrostatic relations for pressure

When the tank is empty, we have the equation as:

$$h_{MR} \cdot SG_{mercury} \cdot \gamma_{water} = \gamma_{water} h$$

$$SG_{mercury} = 13.57$$

$$h = h_{MR} \cdot SG_{mercury} = 150 \text{ mm} \times 13.57 = 2.04 \text{ m}$$

When the tank is filled with water, we assume the mercury interface moves by x :

$$\gamma_{water}(h_{tank} + h + x) = \gamma_{water} \cdot SG_{mercury}(h_{MR} + 2x)$$

$$(3 \text{ m} + 2.04 \text{ m} + x) = 13.57(0.15 \text{ m} + 2x)$$

Thus

$$x = 0.115 \text{ m}$$

The new manometer reading is:

$$h'_{MR} = h_{MR} + 2x = 0.15 \text{ m} + 2 \times 0.115 \text{ m} = 0.38 \text{ m}$$

Problem 3.28

[Difficulty: 2]

3.28 A reservoir manometer is calibrated for use with a liquid of specific gravity 0.827. The reservoir diameter is 5/8 in. and the (vertical) tube diameter is 3/16 in. Calculate the required distance between marks on the vertical scale for 1 in. of water pressure difference.

Given: Reservoir manometer with dimensions shown. The manometer fluid specific gravity is given.

$$D = \frac{5}{8} \cdot \text{in} \quad d = \frac{3}{16} \cdot \text{in} \quad SG_{\text{oil}} = 0.827$$

Find: The required distance between vertical marks on the scale corresponding to Δp of 1 in water.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dz} = -\rho \cdot g \quad (\text{Hydrostatic Pressure - } z \text{ is positive upwards})$$

$$\rho = SG \cdot \rho_{\text{water}} \quad (\text{Definition of Specific Gravity})$$

Assumptions:

- (1) Static liquid
- (2) Incompressible liquid

Integrating the hydrostatic pressure equation we get:

$$\Delta p = -\rho \cdot g \cdot \Delta z$$

Beginning at the free surface of the tank, and accounting for the changes in pressure with elevation:

$$p_{\text{atm}} + \Delta p - \rho_{\text{oil}} \cdot g \cdot (x + h) = p_{\text{atm}}$$

Upon simplification: $\Delta p = \rho_{\text{oil}} \cdot g \cdot (x + h)$ The applied pressure is defined as: $\Delta p = \rho_{\text{water}} \cdot g \cdot l$ where $l = 1 \cdot \text{in}$

Therefore: $\rho_{\text{water}} \cdot g \cdot l = \rho_{\text{oil}} \cdot g \cdot (x + h) \quad x + h = \frac{l}{SG_{\text{oil}}}$

x and h are related through the manometer dimensions: $\frac{\pi}{4} \cdot D^2 \cdot x = \frac{\pi}{4} \cdot d^2 \cdot h \quad x = \left(\frac{d}{D}\right)^2 h$

Solving for h: $h = \frac{l}{SG_{\text{oil}} \cdot \left[1 + \left(\frac{d}{D}\right)^2\right]}$ Substituting values into the expression: $h = \frac{1 \cdot \text{in}}{0.827 \cdot \left[1 + \left(\frac{0.1875 \cdot \text{in}}{0.625 \cdot \text{in}}\right)^2\right]}$

$$h = 1.109 \cdot \text{in}$$

Problem 3.29

[Difficulty: 3]

3.29 The inclined-tube manometer shown has $D = 96$ mm and $d = 8$ mm. Determine the angle, θ , required to provide a 5 : 1 increase in liquid deflection, L , compared with the total deflection in a regular U-tube manometer. Evaluate the sensitivity of this inclined-tube manometer.

Given: Inclined manometer as shown.
 $D = 96 \cdot \text{mm}$ $d = 8 \cdot \text{mm}$
 Angle θ is such that the liquid deflection L is five times that of a regular U-tube manometer.

Find: Angle θ and manometer sensitivity.

Solution: We will apply the hydrostatics equations to this system.

Governing Equation: $\frac{dp}{dz} = -\rho \cdot g$ (Hydrostatic Pressure - z is positive upwards)

Assumptions: (1) Static liquid
 (2) Incompressible liquid

Integrating the hydrostatic pressure equation we get:

$$\Delta p = -\rho \cdot g \cdot \Delta z$$

Applying this equation from point 1 to point 2:

$$p_1 - \rho \cdot g \cdot (x + L \cdot \sin(\theta)) = p_2$$

Upon simplification: $p_1 - p_2 = \rho \cdot g \cdot (x + L \cdot \sin(\theta))$

Since the volume of the fluid must remain constant: $\frac{\pi}{4} \cdot D^2 \cdot x = \frac{\pi}{4} \cdot d^2 \cdot L$ $x = \left(\frac{d}{D}\right)^2 \cdot L$

Therefore: $p_1 - p_2 = \rho \cdot g \cdot L \cdot \left[\left(\frac{d}{D}\right)^2 + \sin(\theta) \right]$

Now for a U-tube manometer: $p_1 - p_2 = \rho \cdot g \cdot h$ Hence: $\frac{p_{1\text{incl}} - p_{2\text{incl}}}{p_{1\text{U}} - p_{2\text{U}}} = \frac{\rho \cdot g \cdot L \cdot \left[\left(\frac{d}{D}\right)^2 + \sin(\theta) \right]}{\rho \cdot g \cdot h}$

For equal applied pressures: $L \cdot \left[\left(\frac{d}{D}\right)^2 + \sin(\theta) \right] = h$ Since $L/h = 5$: $\sin(\theta) = \frac{h}{L} - \left(\frac{d}{D}\right)^2 = \frac{1}{5} - \left(\frac{8 \cdot \text{mm}}{96 \cdot \text{mm}}\right)^2$

$$\theta = 11.13 \cdot \text{deg}$$

The sensitivity of the manometer: $s = \frac{L}{\Delta h_e} = \frac{L}{SG \cdot h}$ $s = \frac{5}{SG}$

Problem 3.30

[Difficulty: 3]

3.30 The inclined-tube manometer shown has $D = 76$ mm and $d = 8$ mm, and is filled with Meriam red oil. Compute the angle, θ , that will give a 15-cm oil deflection along the inclined tube for an applied pressure of 25 mm of water (gage). Determine the sensitivity of this manometer.

Given: Data on inclined manometer

Find: Angle θ for given data; find sensitivity

Solution:

Basic equation $\frac{dp}{dy} = -\rho \cdot g$ or, for constant ρ $\Delta p = \rho \cdot g \cdot \Delta h$ where Δh is height difference

Under applied pressure $\Delta p = SG_{\text{Mer}} \cdot \rho \cdot g \cdot (L \cdot \sin(\theta) + x)$ (1)

From Table A.1 $SG_{\text{Mer}} = 0.827$

and $\Delta p = 1$ in. of water, or $\Delta p = \rho \cdot g \cdot h$ where $h = 25\text{-mm}$ $h = 0.025\text{ m}$

$$\Delta p = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 0.025 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad \Delta p = 245 \text{ Pa}$$

The volume of liquid must remain constant, so $x \cdot A_{\text{res}} = L \cdot A_{\text{tube}}$ $x = L \cdot \frac{A_{\text{tube}}}{A_{\text{res}}} = L \cdot \left(\frac{d}{D}\right)^2$ (2)

Combining Eqs 1 and 2 $\Delta p = SG_{\text{Mer}} \cdot \rho \cdot g \cdot \left[L \cdot \sin(\theta) + L \cdot \left(\frac{d}{D}\right)^2 \right]$

Solving for θ $\sin(\theta) = \frac{\Delta p}{SG_{\text{Mer}} \cdot \rho \cdot g \cdot L} - \left(\frac{d}{D}\right)^2$

$$\sin(\theta) = 245 \cdot \frac{\text{N}}{\text{m}^2} \times \frac{1}{0.827} \times \frac{1}{1000 \cdot \frac{\text{m}^3}{\text{kg}}} \times \frac{1}{9.81 \cdot \frac{\text{s}^2}{\text{m}}} \times \frac{1}{0.15 \cdot \frac{1}{\text{m}}} \times \frac{\text{kg} \cdot \text{m}}{\text{s}^2 \cdot \text{N}} - \left(\frac{8}{76}\right)^2 = 0.186$$

$$\theta = 11\text{-deg}$$

The sensitivity is the ratio of manometer deflection to a vertical water manometer

$$s = \frac{L}{h} = \frac{0.15 \cdot \text{m}}{0.025 \cdot \text{m}} \quad s = 6$$

Problem 3.31

[Difficulty: 4]

3.31 A barometer accidentally contains 6.5 inches of water on top of the mercury column (so there is also water vapor instead of a vacuum at the top of the barometer). On a day when the temperature is 70°F, the mercury column height is 28.35 inches (corrected for thermal expansion). Determine the barometric pressure in psia. If the ambient temperature increased to 85°F and the barometric pressure did not change, would the mercury column be longer, be shorter, or remain the same length? Justify your answer.

Given: Barometer with water on top of the mercury column, Temperature is known:

$$h_2 = 6.5 \cdot \text{in} \quad h_1 = 28.35 \cdot \text{in} \quad SG_{\text{Hg}} = 13.55 \quad (\text{From Table A.2, App. A}) \quad T = 70^\circ \text{F}$$

$$p_v = 0.363 \cdot \text{psi} \quad (\text{From Table A.7, App. A})$$

Find: (a) Barometric pressure in psia
(b) Effect of increase in ambient temperature on length of mercury column for the same barometric pressure: $T_f = 85^\circ \text{F}$

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $\frac{dp}{dh} = -\rho \cdot g$ (Hydrostatic Pressure - h is positive downwards)

$\rho = SG \cdot \rho_{\text{water}}$ (Definition of Specific Gravity)

Assumptions: (1) Static liquid
(2) Incompressible liquid

Integrating the hydrostatic pressure equation we get:

$$\Delta p = \rho \cdot g \cdot \Delta h$$

Start at the free surface of the mercury and progress through the barometer to the vapor pressure of the water:

$$P_{\text{atm}} - \rho_{\text{Hg}} \cdot g \cdot h_1 - \rho_{\text{water}} \cdot g \cdot h_2 = p_v$$

$$P_{\text{atm}} = p_v + \rho_{\text{water}} \cdot g \cdot (SG_{\text{Hg}} \cdot h_1 + h_2)$$

$$P_{\text{atm}} = 0.363 \cdot \frac{\text{lbf}}{\text{in}^2} + 1.93 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}} \times (13.55 \times 28.35 \cdot \text{in} + 6.5 \cdot \text{in}) \times \left(\frac{\text{ft}}{12 \cdot \text{in}} \right)^3 \quad P_{\text{atm}} = 14.41 \cdot \frac{\text{lbf}}{\text{in}^2}$$

At the higher temperature, the vapor pressure of water increases to 0.60 psi. Therefore, if the atmospheric pressure were to remain constant, the length of the mercury column would have to decrease - the increased water vapor would push the mercury out of the tube!

Problem 3.32

[Difficulty: 3]

3.32 A water column stands 50 mm high in a 2.5-mm diameter glass tube. What would be the column height if the surface tension were zero? What would be the column height in a 1.0-mm diameter tube?

Given: Water column standing in glass tube

$$\Delta h = 50 \cdot \text{mm} \quad D = 2.5 \cdot \text{mm} \quad \sigma = 72.8 \times 10^{-3} \frac{\text{N}}{\text{m}}$$

Find: (a) Column height if surface tension were zero.
(b) Column height in 1 mm diameter tube

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards})$$

$$\Sigma F_z = 0 \quad (\text{Static Equilibrium})$$

Assumptions: (1) Static, incompressible liquid
(2) Neglect volume under meniscus
(3) Applied pressure remains constant
(4) Column height is sum of capillary rise and pressure difference

Assumption #4 can be written as: $\Delta h = \Delta h_c + \Delta h_p$

Choose a free-body diagram of the capillary rise portion of the column for analysis:

$$\Sigma F_z = \pi \cdot D \cdot \sigma \cdot \cos(\theta) - \frac{\pi}{4} \cdot D^2 \cdot \rho \cdot g \cdot \Delta h_c = 0 \quad \text{Therefore: } \Delta h_c = \frac{4 \cdot \sigma}{\rho \cdot g \cdot D} \cdot \cos(\theta)$$

Substituting values:

$$\Delta h_c = 4 \times 72.8 \times 10^{-3} \frac{\text{N}}{\text{m}} \times \frac{1}{999} \frac{\text{m}^3}{\text{kg}} \times \frac{1}{9.81} \frac{\text{s}^2}{\text{m}} \times \frac{1}{2.5} \frac{1}{\text{mm}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2} \times \left(\frac{10^3 \cdot \text{mm}}{\text{m}} \right)^2$$

$$\Delta h_c = 11.89 \cdot \text{mm}$$

$$\text{Therefore: } \Delta h_p = \Delta h - \Delta h_c \quad \Delta h_p = 50 \cdot \text{mm} - 11.89 \cdot \text{mm}$$

$$\Delta h_p = 38.1 \cdot \text{mm} \quad (\text{result for } \sigma = 0)$$

For the 1 mm diameter tube:

$$\Delta h_c = 4 \times 72.8 \times 10^{-3} \frac{\text{N}}{\text{m}} \times \frac{1}{999} \frac{\text{m}^3}{\text{kg}} \times \frac{1}{9.81} \frac{\text{s}^2}{\text{m}} \times \frac{1}{1} \frac{1}{\text{mm}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2} \times \left(\frac{10^3 \cdot \text{mm}}{\text{m}} \right)^2$$

$$\Delta h_c = 29.71 \cdot \text{mm}$$

$$\Delta h = 29.7 \cdot \text{mm} + 38.1 \cdot \text{mm}$$

$$\Delta h = 67.8 \cdot \text{mm}$$

Problem 3.33

[Difficulty :2]

3.33 Consider a small-diameter open-ended tube inserted at the interface between two immiscible fluids of different densities. Derive an expression for the height difference Δh between the interface level inside and outside the tube in terms of tube diameter D , the two fluid densities ρ_1 and ρ_2 , and the surface tension σ and angle θ for the two fluids' interface. If the two fluids are water and mercury, find the height difference if the tube diameter is 40 mils (1 mil = 0.001 in.).

Given: Two fluids inside and outside a tube

Find: (a) An expression for height Δh
(b) Height difference when $D = 0.040$ in for water/mercury

Assumptions: (1) Static, incompressible fluids
(2) Neglect meniscus curvature for column height and volume calculations

Solution:

A free-body vertical force analysis for the section of fluid 1 height Δh in the tube below the "free surface" of fluid 2 leads to

$$\sum F = 0 = \Delta p \cdot \frac{\pi \cdot D^2}{4} - \rho_1 \cdot g \cdot \Delta h \cdot \frac{\pi \cdot D^2}{4} + \pi \cdot D \cdot \sigma \cdot \cos(\theta)$$

where Δp is the pressure difference generated by fluid 2 over height Δh , $\Delta p = \rho_2 \cdot g \cdot \Delta h$

Hence

$$\Delta p \cdot \frac{\pi \cdot D^2}{4} - \rho_1 \cdot g \cdot \Delta h \cdot \frac{\pi \cdot D^2}{4} = \rho_2 \cdot g \cdot \Delta h \cdot \frac{\pi \cdot D^2}{4} - \rho_1 \cdot g \cdot \Delta h \cdot \frac{\pi \cdot D^2}{4} = -\pi \cdot D \cdot \sigma \cdot \cos(\theta)$$

Solving for Δh

$$\Delta h = -\frac{4 \cdot \sigma \cdot \cos(\theta)}{g \cdot D \cdot (\rho_2 - \rho_1)}$$

For fluids 1 and 2 being water and mercury (for mercury $\sigma = 375$ mN/m and $\theta = 140^\circ$, from Table A.4), solving for Δh when $D = 0.040$ in

$$\Delta h = -4 \times 0.375 \cdot \frac{\text{N}}{\text{m}} \times \frac{\text{lbf}}{4.448 \cdot \text{N}} \times \frac{0.0254 \text{ m}}{\text{in}} \times \cos(140^\circ) \times \frac{\text{s}^2}{32.2 \cdot \text{ft}} \times \frac{1}{0.040 \cdot \text{in}} \times \frac{\text{ft}^3}{1.94 \cdot \text{slug}} \times \left(\frac{12 \cdot \text{in}}{\text{ft}} \right)^3 \times \frac{1}{(13.6 - 1)} \times \frac{\text{slug} \cdot \text{ft}}{\text{lbf} \cdot \text{s}^2}$$

$$\Delta h = 0.360 \cdot \text{in}$$

Problem 3.34

[Difficulty: 2]

3.34 Compare the height due to capillary action of water exposed to air in a circular tube of diameter $D = 0.5$ mm, and between two infinite vertical parallel plates of gap $a = 0.5$ mm.

Given: Water in a tube or between parallel plates

Find: Height Δh for each system

Solution:

a) Tube: A free-body vertical force analysis for the section of water height Δh above the "free surface" in the tube, as shown in the figure, leads to

$$\sum F = 0 = \pi \cdot D \cdot \sigma \cdot \cos(\theta) - \rho \cdot g \cdot \Delta h \cdot \frac{\pi \cdot D^2}{4}$$

Assumption: Neglect meniscus curvature for column height and volume calculations

Solving for Δh

$$\Delta h = \frac{4 \cdot \sigma \cdot \cos(\theta)}{\rho \cdot g \cdot D}$$

b) Parallel Plates: A free-body vertical force analysis for the section of water height Δh above the "free surface" between plates arbitrary width w (similar to the figure above), leads to

$$\sum F = 0 = 2 \cdot w \cdot \sigma \cdot \cos(\theta) - \rho \cdot g \cdot \Delta h \cdot w \cdot a$$

Solving for Δh

$$\Delta h = \frac{2 \cdot \sigma \cdot \cos(\theta)}{\rho \cdot g \cdot a}$$

For water $\sigma = 72.8$ mN/m and $\theta = 0^\circ$ (Table A.4), so

a) Tube	$\Delta h = \frac{4 \times 0.0728 \cdot \frac{\text{N}}{\text{m}}}{999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 0.005 \cdot \text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2}$	$\Delta h = 5.94 \times 10^{-3} \text{ m}$	$\Delta h = 5.94 \cdot \text{mm}$
b) Parallel Plates	$\Delta h = \frac{2 \times 0.0728 \cdot \frac{\text{N}}{\text{m}}}{999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 0.005 \cdot \text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2}$	$\Delta h = 2.97 \times 10^{-3} \text{ m}$	$\Delta h = 2.97 \cdot \text{mm}$

Problem 3.35

[Difficulty: 3]

3.35

Based on the atmospheric temperature data of the U.S. Standard Atmosphere of Fig. 3.3, compute and plot the pressure variation with altitude, and compare with the pressure data of Table A.3.

Given: Atmospheric temperature data

Find: Pressure variation; compare to Table A.3

Solution:

From Section 3-3:

$$\frac{dp}{dz} = -\rho \cdot z$$

For a linear temperature variation

$$m = -\frac{dT}{dz} = \text{const} \quad p = p_0 \cdot \left(\frac{T}{T_0} \right)^{\frac{g}{m \cdot R}}$$

For isothermal conditions (Example 3.4)

$$p = p_0 \cdot e^{-\frac{g \cdot (z - z_0)}{R \cdot T}}$$

In these equations p_0 , T_0 , and z_0 are reference conditions

$$\begin{aligned} p_{SL} &= 101 \text{ kPa} \\ R &= 286.9 \text{ J/kg} \cdot \text{K} \\ \rho &= 999 \text{ kg/m}^3 \end{aligned}$$

The temperature can be computed from the data in the figure.
The pressures are then computed from the appropriate equation.

From Table A.3

Agreement between calculated and tabulated data is very good (as it should be, considering the table data are also computed!)

Problem 3.36

[Difficulty: 3]

3.36 At ground level in Denver, Colorado, the atmospheric pressure and temperature are 83.2 kPa and 25°C. Calculate the pressure on Pike's Peak at an elevation of 2690 m above the city assuming (a) an incompressible and (b) an adiabatic atmosphere. Plot the ratio of pressure to ground level pressure in Denver as a function of elevation for both cases.

Given: Atmospheric conditions at ground level ($z = 0$) in Denver, Colorado are $p_0 = 83.2$ kPa, $T_0 = 25^\circ\text{C}$. Pike's peak is at elevation $z = 2690$ m.

Find: p/p_0 vs z for both cases.

Solution:

Governing Equations: $\frac{dp}{dz} = -\rho \cdot g$ $p = \rho \cdot R \cdot T$

Assumptions: (1) Static fluid
(2) Ideal gas behavior

(a) For an incompressible atmosphere:

$$\frac{dp}{dz} = -\rho \cdot g \quad \text{becomes} \quad p - p_0 = -\int_0^z \rho \cdot g \, dz \quad \text{or} \quad p = p_0 - \rho_0 \cdot g \cdot z = p_0 \cdot \left(1 - \frac{g \cdot z}{R \cdot T_0}\right) \quad (1)$$

At $z = 2690 \cdot \text{m}$ $p = 83.2 \cdot \text{kPa} \times \left(1 - 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2690 \cdot \text{m} \times \frac{\text{kg} \cdot \text{K}}{287 \cdot \text{N} \cdot \text{m}} \times \frac{1}{298 \cdot \text{K}} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}\right) \quad p = 57.5 \cdot \text{kPa}$

(b) For an adiabatic atmosphere: $\frac{p}{\rho^k} = \text{const} \quad \rho = \rho_0 \cdot \left(\frac{p}{p_0}\right)^{\frac{1}{k}}$

$$\frac{dp}{dz} = -\rho \cdot g \quad \text{becomes} \quad dp = -\rho_0 \cdot \left(\frac{p}{p_0}\right)^{\frac{1}{k}} \cdot g \cdot dz \quad \text{or} \quad \frac{1}{p^{\frac{1}{k}}} dp = -\frac{\rho_0 \cdot g}{p_0^{\frac{1}{k}}} \cdot dz$$

But $\int_{p_0}^p \frac{1}{p^{\frac{1}{k}}} dp = \frac{k}{k-1} \cdot (p - p_0)^{\frac{k-1}{k}} \quad \text{hence} \quad \frac{k}{k-1} \cdot \left(p^{\frac{k-1}{k}} - p_0^{\frac{k-1}{k}}\right) = -\frac{\rho_0 \cdot g}{p_0^{\frac{1}{k}}} \cdot z$

Solving for the pressure ratio $\frac{p}{p_0} = \left(1 - \frac{k-1}{k} \cdot \frac{\rho_0}{p_0} \cdot g \cdot z\right)^{\frac{k}{k-1}} \quad \text{or} \quad \frac{p}{p_0} = \left(1 - \frac{k-1}{k} \cdot \frac{g \cdot z}{R \cdot T_0}\right)^{\frac{k}{k-1}} \quad (2)$

At $z = 2690 \cdot \text{m}$ $p = 83.2 \cdot \text{kPa} \times \left(1 - \frac{1.4-1}{1.4} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2690 \cdot \text{m} \times \frac{\text{kg} \cdot \text{K}}{287 \cdot \text{N} \cdot \text{m}} \times \frac{1}{298 \cdot \text{K}} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}\right)^{\frac{1.4}{1.4-1}} \quad p = 60.2 \cdot \text{kPa}$

Equations 1 and 2 can be plotted:

Problem 3.37

(Difficulty: 2)

3.37 If atmospheric pressure at the ground is 101.3 kPa and temperature is 15°C , calculate the pressure 7.62 km above the ground, assuming (a) no density variation, (b) isothermal variation of density with pressure, and (c) adiabatic variation of density with pressure.

Assumption: Atmospheric air is stationary and behaves as an ideal gas.

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$\frac{dp}{dz} = -\rho g = -\gamma$$

- (a) For this case with no density variation, we integrate with respect to z from the ground level pressure p_0 to the pressure at any height h . The pressure is

$$p = p_0 - \gamma h$$

From Table A.10, the density of air at sea level is

$$\rho = 1.23 \frac{\text{kg}}{\text{m}^3}$$

Or the specific weight is

$$\gamma = \rho g = 1.23 \frac{\text{kg}}{\text{m}^3} \times 9.81 \frac{\text{m}}{\text{s}^2} = 12.07 \frac{\text{N}}{\text{m}^3}$$

Thus the pressure at 7.62 km is

$$p = 101.3 \text{ kPa} - 12.07 \frac{\text{N}}{\text{m}^3} \times 7.62 \times 1000 \text{ m} = 9.63 \text{ kPa}$$

- (b) For isothermal condition we have for an ideal gas:

$$\frac{p}{\rho} = \frac{p_0}{\rho_0} = RT = \text{constant}$$

Therefore, since $\rho = \gamma/g$ and g is a constant

$$\frac{p}{\gamma} = \frac{p_0}{\gamma_0} = \frac{101.3 \text{ kPa}}{12.07 \frac{\text{N}}{\text{m}^3}} = 8420 \text{ m} = \text{constant}$$

From the hydrostatic relation we have:

$$dp = -\gamma dz$$

$$\frac{dp}{p} = -\frac{\gamma}{p} dz$$

$$\int_{p_0}^p \frac{dp}{p} = -\frac{1}{8420m} \int_0^z dz$$

$$\ln\left(\frac{p}{p_0}\right) = -\frac{1}{8420m} z$$

Thus the pressure at 7.62 km is

$$\frac{p}{p_0} = e^{-\frac{7620m}{8420m}} = e^{-0.905} = 0.4045$$

$$p = 101.3kPa \times 0.4045 = 41.0 kPa$$

(c) For a reversible and adiabatic variation of density we have:

$$pv^k = \frac{p}{\rho^k} = \text{constant}$$

Where k is the specific heat ratio

$$k = 1.4$$

Or, since gravity g is constant, we can write in terms of the specific weight

$$\frac{p}{\gamma^k} = \frac{p_0}{\gamma_0^k} = \text{constant}$$

Or the specific weight is

$$\gamma = \gamma_0 \left(\frac{p}{p_0}\right)^{1/k}$$

The hydrostatic expression becomes

$$dp = -\gamma_0 \left(\frac{p}{p_0}\right)^{1/k} dz$$

Separating variables

$$\frac{p_0^{1/k}}{\gamma_0} \int_{p_0}^p \frac{dp}{(p)^{1/k}} = - \int_0^z dz$$

Integrating between the limits $p=p_0$ at $z=0$ and $p = p$ at $z = z$

$$\left(\frac{k}{k-1}\right) \frac{p_0^{1/k}}{\gamma_0} \left[p^{\frac{k-1}{k}} - p_0^{\frac{k-1}{k}} \right] = -z$$

Or

$$\left(\frac{p}{p_0}\right)^{\frac{k-1}{k}} = 1 - \left(\frac{k-1}{k}\right) \frac{\gamma_0 z}{p_0}$$

The pressure is then

$$p = p_0 \left[1 - \left(\frac{k-1}{k}\right) \frac{\gamma_0 z}{p_0} \right]^{k/(k-1)} = 101.3kPa \left[1 - \left(\frac{1.4-1}{1.4}\right) \times \frac{12.07 \frac{N}{m^3} \times 7620m}{101.3 \times 1000 Pa} \right]^{1.4/1.4-1}$$

$$p = 35.4 kPa$$

The calculation of pressure depends heavily on the assumption we make about how density changes.

Problem 3.38

(Difficulty: 2)

3.38 If the temperature in the atmosphere is assumed to vary linearly with altitude so $T = T_0 - \alpha z$ where T_0 is the sea level temperature and $\alpha = -dT/dz$ is the temperature lapse rate, find $p(z)$ when air is taken to be a perfect gas. Give the answer in terms of p_0 , α , g , R , and z only.

Assumption: Atmospheric air is stationary and behaves as an ideal gas.

Solution: Use the hydrostatic relation to find the pressures in the fluid

Governing equation: Hydrostatic pressure in a liquid, with z measured upward:

$$dp = -\gamma dz$$

The ideal gas relation is

$$\frac{p}{\rho} = RT$$

Or in terms of the specific weight, the pressure is

$$p = \rho RT = \frac{\gamma}{g} RT$$

Relating the temperature to the adiabatic lapse rate

$$p = \frac{\gamma}{g} R(T_0 - \alpha z)$$

Inserting the expression for specific weight into the hydrostatic equation

$$dp = - \frac{gp}{R(T_0 - \alpha z)} dz$$

Separating variables

$$\frac{dp}{p} = - \frac{g}{R} \frac{dz}{(T_0 - \alpha z)}$$

Integrating between the surface and any height z

$$\int_{p_0}^p \frac{dp}{p} = - \frac{g}{R} \int_0^z \frac{dz}{(T_0 - \alpha z)}$$

Or

$$\ln\left(\frac{p}{p_0}\right) = - \frac{g}{R} \ln\left(\frac{T_0 - \alpha z}{T_0}\right)$$

In terms of p

$$\frac{p}{p_0} = \left(1 - \frac{\alpha z}{T_0}\right)^{g/\alpha R}$$

Problem 3.39

[Difficulty: 3]

3.39 A door 1 m wide and 1.5 m high is located in a plane vertical wall of a water tank. The door is hinged along its upper edge, which is 1 m below the water surface. Atmospheric pressure acts on the outer surface of the door and at the water surface. (a) Determine the magnitude and line of action of the total resultant force from all fluids acting on the door. (b) If the water surface gage pressure is raised to 0.3 atm, what is the resultant force and where is its line of action? (c) Plot the ratios F/F_0 and y'/y_c for different values of the surface pressure ratio p_s/p_{atm} . (F_0 is the resultant force when $p_s = p_{atm}$.)

Given: Door located in plane vertical wall of water tank as shown

$$a = 1.5 \text{ m} \quad b = 1 \text{ m} \quad c = 1 \text{ m}$$

Atmospheric pressure acts on outer surface of door.

Find: Resultant force and line of action:

(a) for $p_s = p_{atm}$

(b) for $p_{sg} = 0.3 \text{ atm}$

Plot F/F_0 and y'/y_c over range of p_s/p_{atm} (F_0 is force determined in (a), y_c is y-coordinate of door centroid).

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dy} = \rho \cdot g \quad \text{(Hydrostatic Pressure - } y \text{ is positive downwards)}$$

$$F_R = \int p \, dA \quad \text{(Hydrostatic Force on door)}$$

$$y' \cdot F_R = \int y \cdot p \, dA \quad \text{(First moment of force)}$$

Assumptions: (1) Static fluid
(2) Incompressible fluid

We will obtain a general expression for the force and line of action, and then simplify for parts (a) and (b).

Since $dp = \rho \cdot g \cdot dh$ it follows that $p = p_s + \rho \cdot g \cdot y$

Now because p_{atm} acts on the outside of the door, p_{sg} is the surface gage pressure: $p = p_{sg} + \rho \cdot g \cdot y$

$$F_R = \int p \, dA = \int_c^{c+a} p \cdot b \, dy = \int_c^{c+a} (p_{sg} + \rho \cdot g \cdot y) \cdot b \, dy = b \cdot \left[p_{sg} \cdot a + \frac{\rho \cdot g}{2} \cdot (a^2 + 2 \cdot a \cdot c) \right] \quad (1)$$

$$y' \cdot F_R = \int y \cdot p \, dA \quad \text{Therefore:} \quad y' = \frac{1}{F_R} \int y \cdot p \, dA = \frac{1}{F_R} \cdot \int_c^{c+a} y \cdot (p_{sg} + \rho \cdot g \cdot y) \cdot b \, dy$$

$$\text{Evaluating the integral:} \quad y' = \frac{b}{F_R} \left[\frac{p_{sg}}{2} [(c+a)^2 - c^2] + \frac{\rho \cdot g}{3} [(c+a)^3 - c^3] \right]$$

$$\text{Simplifying: } y' = \frac{b}{F_R} \cdot \left[\frac{p_{sg}}{2} (a^2 + 2 \cdot a \cdot c) + \frac{\rho \cdot g}{3} \cdot [a^3 + 3 \cdot a \cdot c \cdot (a + c)] \right] \quad (2)$$

For part (a) we know $p_{sg} = 0$ so substituting into (1) we get: $F_o = \frac{\rho \cdot g \cdot b}{2} \cdot (a^2 + 2 \cdot a \cdot c)$

$$F_o = \frac{1}{2} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 1 \cdot \text{m} \times [(1.5 \cdot \text{m})^2 + 2 \times 1.5 \cdot \text{m} \times 1 \cdot \text{m}] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad F_o = 25.7 \cdot \text{kN}$$

Substituting into (2) for the line of action we get: $y' = \frac{\rho \cdot g \cdot b}{3 \cdot F_o} \cdot [a^3 + 3 \cdot a \cdot c \cdot (a + c)]$

$$y' = \frac{1}{3} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 1 \cdot \text{m} \cdot \frac{1}{25.7 \times 10^3 \text{ N}} \cdot \frac{1}{\text{N}} \times [(1.5 \cdot \text{m})^3 + 3 \times 1.5 \cdot \text{m} \times 1 \cdot \text{m} \times (1.5 \cdot \text{m} + 1 \cdot \text{m})] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad y' = 1.9 \text{ m}$$

For part (b) we know $p_{sg} = 0.3 \cdot \text{atm}$. Substituting into (1) we get:

$$F_R = 1 \cdot \text{m} \times \left[0.3 \cdot \text{atm} \times \frac{1.013 \times 10^5 \cdot \text{N}}{\text{m}^2 \cdot \text{atm}} \times 1.5 \cdot \text{m} + \frac{1}{2} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times [(1.5 \cdot \text{m})^2 + 2 \times 1.5 \cdot \text{m} \times 1 \cdot \text{m}] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \right] \quad F_R = 71.3 \cdot \text{kN}$$

$$y' = \frac{1 \cdot \text{m} \times \left[\frac{0.3 \cdot \text{atm}}{2} \times \frac{1.013 \times 10^5 \cdot \text{N}}{\text{m}^2 \cdot \text{atm}} \times [(1.5)^2 + 2 \cdot 1.5 \cdot 1] \cdot \text{m}^2 + \frac{999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2}}{3} \times [(1.5)^3 + 3 \cdot 1.5 \cdot 1 \cdot (1.5 + 1)] \cdot \text{m}^3 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \right]}{71.3 \times 10^3 \cdot \text{N}} \quad y' = 1.789 \text{ m}$$

The value of F/F_o is obtained from Eq. (1) and our result from part (a):

$$\frac{F}{F_o} = \frac{b \cdot \left[p_{sg} \cdot a + \frac{\rho \cdot g}{2} \cdot (a^2 + 2 \cdot a \cdot c) \right]}{\frac{\rho \cdot g \cdot b}{2} \cdot (a^2 + 2 \cdot a \cdot c)} = 1 + \frac{2 \cdot p_{sg}}{\rho \cdot g \cdot (a + 2 \cdot c)}$$

For the gate $y_c = c + \frac{a}{2}$ Therefore, the value of y'/y_c is obtained from Eqs. (1) and (2):

$$\frac{y'}{y_c} = \frac{2 \cdot b}{F_R \cdot (2 \cdot c + a)} \cdot \left[\frac{p_{sg}}{2} (a^2 + 2 \cdot a \cdot c) + \frac{\rho \cdot g}{3} \cdot [a^3 + 3 \cdot a \cdot c \cdot (a + c)] \right] = \frac{2 \cdot b}{(2 \cdot c + a)} \cdot \frac{\left[\frac{p_{sg}}{2} (a^2 + 2 \cdot a \cdot c) + \frac{\rho \cdot g}{3} \cdot [a^3 + 3 \cdot a \cdot c \cdot (a + c)] \right]}{\left[b \cdot \left[p_{sg} \cdot a + \frac{\rho \cdot g}{2} \cdot (a^2 + 2 \cdot a \cdot c) \right] \right]}$$

Simplifying this expression we get:

$$\frac{y'}{y_c} = \frac{2}{(2 \cdot c + a)} \cdot \frac{\frac{p_{sg}}{2}(a^2 + 2 \cdot a \cdot c) + \frac{\rho \cdot g}{3} \cdot [a^3 + 3 \cdot a \cdot c \cdot (a + c)]}{p_{sg} \cdot a + \frac{\rho \cdot g}{2} \cdot (a^2 + 2 \cdot a \cdot c)}$$

Based on these expressions we see that the force on the gate varies linearly with the increase in surface pressure, and that the line of action of the resultant is always below the centroid of the gate. As the pressure increases, however, the line of action moves closer to the centroid.

Plots of both ratios are shown below:

3.40 A hydropneumatic elevator consists of a piston-cylinder assembly to lift the elevator cab. Hydraulic oil, stored in an accumulator tank pressurized by air, is valved to the piston as needed to lift the elevator. When the elevator descends, oil is returned to the accumulator. Design the least expensive accumulator that can satisfy the system requirements. Assume the lift is 3 floors, the maximum load is 10 passengers, and the maximum system pressure is 800 kPa (gage). For column bending strength, the piston diameter must be at least 150 mm. The elevator cab and piston have a combined mass of 3000 kg, and are to be purchased. Perform the analysis needed to define, as a function of system operating pressure, the piston diameter, the accumulator volume and diameter, and the wall thickness. Discuss safety features that your company should specify for the complete elevator system. Would it be preferable to use a completely pneumatic design or a completely hydraulic design? Why?

Discussion: The design requirements are specified except that a typical floor height is about 12 ft, making the total required lift about 36 ft. A spreadsheet was used to calculate the system properties for various pressures. Results are presented on the next page, followed by a sample calculation. Total cost dropped quickly as system pressure was increased. A shallow minimum was reached in the 100-110 psig range. The lowest-cost solution was obtained at a system pressure of about 100 psig. At this pressure, the reservoir of 140 gal required a 3.30 ft diameter pressure sphere with a 0.250 in wall thickness. The welding cost was \$155 and the material cost \$433, for a total cost of \$588. Accumulator wall thickness was constrained at 0.250 in for pressures below 100 psi; it increased for higher pressures (this caused the discontinuity in slope of the curve at 100 psig). The mass of steel became constant above 110 psig. No allowance was made for the extra volume needed to pressurize the accumulator. Fail-safe design is essential for an elevator to be used by the public. The control circuitry should be redundant. Failures must be easy to spot. For this reason, hydraulic actuation is good: leaks will be readily apparent. The final design must be reviewed, approved, and stamped by a professional engineer since the design involves public safety. The terminology used in the solution is defined in the following table:

Symbol	Definition	Units
p	System pressure	psig
A_p	Area of lift piston	in ²
V_{oil}	Volume of oil	gal
D_s	Diameter of spherical accumulator	ft
t	Wall thickness of accumulator	in
A_w	Area of weld	in ²
C_w	Cost of weld	\$
M_s	Mass of steel accumulator	lbm
C_s	Cost of steel	\$
C_t	Total Cost	\$

A sample calculation and the results of the system simulation in Excel are presented below.

Sample calculation for a pressure of 20 psig:

$$W_t = p \cdot A_p \quad A_p = \frac{W_t}{p} \quad A_p = 7500 \cdot \text{lbf} \times \frac{1}{20} \cdot \frac{\text{in}^2}{\text{lbf}} \quad A_p = 375 \cdot \text{in}^2$$

$$V_{\text{oil}} = A_p \cdot L \quad V_{\text{oil}} = 375 \cdot \text{in}^2 \times 36 \cdot \text{ft} \times \left(\frac{\text{ft}}{12 \cdot \text{in}} \right)^2 \times \frac{7.48 \cdot \text{gal}}{\text{ft}^3} \quad V_{\text{oil}} = 701 \cdot \text{gal}$$

$$V_{\text{oil}} = V_s = \frac{4}{3} \cdot \pi \cdot R_s^3 = \frac{\pi}{6} \cdot D_s^3 \quad D_s = \left(\frac{6 \cdot V_{\text{oil}}}{\pi} \right)^{\frac{1}{3}} \quad D_s = \left(\frac{6}{\pi} \times 701 \cdot \text{gal} \times \frac{\text{ft}^3}{7.48 \cdot \text{gal}} \right)^{\frac{1}{3}} \quad D_s = 5.64 \cdot \text{ft}$$

From a force balance on the sphere:

$$\text{Thus: } p \cdot \pi \cdot \frac{D_s^2}{4} = \pi \cdot D_s \cdot t \cdot \sigma, \text{ so } t = \frac{p}{\sigma} \cdot \frac{D_s}{4} \quad t = 20 \cdot \frac{\text{lbf}}{\text{in}^2} \times \frac{1}{4000} \cdot \frac{\text{in}^2}{\text{lbf}} \times \frac{5.64 \cdot \text{ft}}{4} \times \frac{12 \cdot \text{in}}{\text{ft}} \quad t = 0.085 \cdot \text{in}$$

Since the minimum wall thickness is 0.250 in: t = 0.250 in

$$A_w = \pi \cdot D_s \cdot t \quad A_w = \pi \cdot 5.64 \cdot \text{ft} \cdot 0.250 \cdot \text{in} \cdot \frac{12 \cdot \text{in}}{\text{ft}} \quad A_w = 53.2 \cdot \text{in}^2$$

$$C_w = 5.00 \cdot \frac{1}{\text{in}^2} \times 53.2 \cdot \text{in}^2 \quad (\text{cost in \$}) \quad C_w = 266$$

$$M_s = 4 \cdot \pi \cdot R_s^2 \cdot t \cdot \rho_s = \pi \cdot D_s^2 \cdot t \cdot SG_s \cdot \rho_{\text{water}}$$

$$M_s = \pi \times (5.64 \cdot \text{ft})^2 \times 0.250 \cdot \text{in} \times \frac{\text{ft}}{12 \cdot \text{in}} \times 7.8 \times 62.4 \cdot \frac{\text{lbm}}{\text{ft}^3} \quad M_s = 1013 \cdot \text{lbm}$$

$$C_s = 1.25 \cdot \frac{1}{\text{lbm}} \times 1013 \cdot \text{lbm} \quad (\text{cost in \$}) \quad C_s = 1266$$

Therefore the total cost is:

$$C_t = 266 + 1266 \quad (\text{cost in \$}) \quad C_t = 1532$$

Problem 3.41

[Difficulty: 3]

3.41 Semicircular plane gate AB is hinged along B and held by horizontal force F_A applied at A . The liquid to the left of the gate is water. Calculate the force F_A required for equilibrium.

Given: Geometry of gate

Find: Force F_A for equilibrium

Solution:

Basic equation $F_R = \int p \, dA$ $\frac{dp}{dh} = \rho \cdot g$ $\Sigma M_Z = 0$

or, use computing equations $F_R = p_c \cdot A$ $y' = y_c + \frac{I_{xx}}{A \cdot y_c}$ where y would be measured from the free surface

Assumptions: static fluid; $\rho = \text{constant}$; p_{atm} on other side; door is in equilibrium

Instead of using either of these approaches, we note the following, using y as in the sketch

$$\Sigma M_Z = 0 \quad F_A \cdot R = \int y \cdot p \, dA \quad \text{with} \quad p = \rho \cdot g \cdot h \quad \text{(Gage pressure, since } p = p_{\text{atm}} \text{ on other side)}$$

$$F_A = \frac{1}{R} \cdot \int y \cdot \rho \cdot g \cdot h \, dA \quad \text{with} \quad dA = r \cdot dr \cdot d\theta \quad \text{and} \quad y = r \cdot \sin(\theta) \quad h = H - y$$

Hence
$$F_A = \frac{1}{R} \cdot \int_0^\pi \int_0^R \rho \cdot g \cdot r \cdot \sin(\theta) \cdot (H - r \cdot \sin(\theta)) \cdot r \, dr \, d\theta = \frac{\rho \cdot g}{R} \cdot \int_0^\pi \left(\frac{H \cdot R^3}{3} \cdot \sin(\theta) - \frac{R^4}{4} \cdot \sin^2(\theta) \right) d\theta$$

$$F_R = \frac{\rho \cdot g}{R} \cdot \left(\frac{2 \cdot H \cdot R^3}{3} - \frac{\pi \cdot R^4}{8} \right) = \rho \cdot g \cdot \left(\frac{2 \cdot H \cdot R^2}{3} - \frac{\pi \cdot R^3}{8} \right)$$

Using given data
$$F_R = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times \left[\frac{2}{3} \times 25 \cdot \text{ft} \times (10 \cdot \text{ft})^2 - \frac{\pi}{8} \times (10 \cdot \text{ft})^3 \right] \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}} \quad F_R = 7.96 \times 10^4 \cdot \text{lbf}$$

Problem 3.42

(Difficulty: 2)

3.42 A circular gate 3 m in diameter has its center 2.5 m below a water surface and lies in a plane sloping at 60°. Calculate magnitude, direction and location of total force on the gate.

Find: The direction, magnitude of the total force F .

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure, force, and moments, with y measured from the surface of the liquid:

$$\frac{dp}{dy} = \rho g = \gamma$$

$$F_R = \int p dA$$

$$y' F_R = \int y p dA$$

For the magnitude of the force we have:

$$F = \int_A p dA$$

A free body diagram of the gate is

The pressure on the gate is the pressure at the centroid, which is $y_c = 2.5$ m. So the force can be calculated as:

$$F = \rho g h_c A = 999 \frac{\text{kg}}{\text{m}^3} \times 9.81 \frac{\text{m}}{\text{s}^2} \times 2.5 \text{ m} \times \frac{\pi}{4} \times (3 \text{ m})^2 = 173200 \text{ N} = 173.2 \text{ kN}$$

The direction is perpendicular to the gate.

For the location of the force we have:

$$y' = y_c + \frac{I_{\hat{x}\hat{x}}}{Ay_c}$$

The y axis is along the plate so the distance to the centroid is:

$$y_c = \frac{2.5 \text{ m}}{\sin 60^\circ} = 2.89 \text{ m}$$

The area moment of inertia is

$$I_{\hat{x}\hat{x}} = \frac{\pi D^4}{64} = \frac{\pi}{64} \times (3 \text{ m})^4 = 3.976 \text{ m}^4$$

The area is

$$A = \frac{\pi}{4} D^2 = \frac{\pi}{4} \times (3 \text{ m})^2 = 7.07 \text{ m}^2$$

So

$$y' = 2.89 \text{ m} + \frac{3.976 \text{ m}^4}{7.07 \text{ m}^2 \times 2.89 \text{ m}} = 2.89 \text{ m} + 0.1946 \text{ m} = 3.08 \text{ m}$$

The vertical location on the plate is

$$h' = y' \sin 60^\circ = 3.08 \text{ m} \times \frac{\sqrt{3}}{2} = 2.67 \text{ m}$$

The force acts on the point which has the depth of 2.67 m.

Problem 3.43

(Difficulty: 2)

3.43 For the situation shown, find the air pressure in the tank in psi. Calculate the force exerted on the gate at the support B if the gate is 10 ft wide. Show a free body diagram of the gate with all the forces drawn in and their points of application located.

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure and force, and the static relation for moments:

$$\frac{dp}{dy} = \rho g = \gamma$$

The specific weight for water is:

$$\gamma = 62.4 \frac{\text{lbf}}{\text{ft}^3}$$

The pressure of the air equals that at the surface of the water in the tank. As shown by the manometer, the pressure at the surface is less than atmospheric due to the three foot head of water. The gage pressure of the air is then:

$$p_{air} = -\gamma h = -62.4 \frac{\text{lbf}}{\text{ft}^3} \times 3\text{ft} = -187.2 \frac{\text{lbf}}{\text{ft}^2}$$

A free body diagram for the gate is

For the force in the horizontal direction, we have:

$$F_1 = \gamma h_c A = 62.4 \frac{\text{lb}}{\text{ft}^3} \times 3 \text{ ft} \times (6 \text{ ft} \times 10 \text{ ft}) = 11230 \text{ lbf}$$

$$F_2 = p_{air} A = -187.2 \frac{\text{lb}}{\text{ft}^2} \times (8 \text{ ft} \times 10 \text{ ft}) = 14980 \text{ lbf}$$

With the momentum balance about hinge we have:

$$\sum M = F_1 h_c - Ph - F_2 \frac{h}{2} = 11230 \text{ lbf} \times 6 \text{ ft} - P \times 8 \text{ ft} - 14980 \text{ lbf} \times 4 \text{ ft} = 0$$

So the force exerted on B is:

$$P = 933 \text{ lbf}$$

Problem 3.44

(Difficulty: 3)

3.44 What is the pressure at A? Draw a free body diagram of the 10 ft wide gate showing all forces and locations of their lines of action. Calculate the minimum force P necessary to keep the gate closed.

Given: All the parameters are shown in the figure.

Find: The pressure p_A . The minimum force P necessary to keep the gate closed.

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure, force, and moments, with y measured from the surface of the liquid:

$$\frac{dp}{dy} = \rho g = \gamma$$

$$F_R = \int p dA$$

$$y' F_R = \int y p dA$$

The specific weight of the water is:

$$\gamma_{water} = 62.4 \frac{lbf}{ft^3}$$

The gage pressure at A is given by integrating the hydrostatic relation:

$$p_A = \gamma_{oil} h_A = SG \gamma_{oil} h_A = 0.9 \times 62.4 \frac{lbf}{ft^3} \times 6 ft = 337 \frac{lbf}{ft^2}$$

A free body diagram of the gate is

The horizontal force F_1 as shown in the figure is given by the pressure at the centroid of the submerged area (3 ft):

$$F_1 = \gamma_{oil} h_c A = 0.9 \times 62.4 \frac{lb}{ft^3} \times 3 ft \times (6 ft \times 10 ft) = 10110 lb$$

The vertical force F_2 is given by the pressure at the depth of the surface (4 ft)

$$F_2 = p_A A = 337 \frac{lb}{ft^2} \times (4 ft \times 10 ft) = 13480 lb$$

The force F_1 acts two-thirds of the distance down from the water surface and the force F_2 acts at the centroid..

Taking the moments about the hinge:

$$-F_1 \times 6 ft - F_2 \times 2 ft + P \times 4 ft = 0$$

So we have for the force at the support:

$$P = \frac{10110 lb \times 6 ft + 13480 lb \times 2 ft}{4 ft} = 21900 lb$$

Problem 3.45

[Difficulty: 3]

3.45 A plane gate of uniform thickness holds back a depth of water as shown. Find the minimum weight needed to keep the gate closed.

Given: Geometry of plane gate

Find: Minimum weight to keep it closed

Solution:

Basic equation $F_R = \int p \, dA$ $\frac{dp}{dh} = \rho \cdot g$ $\Sigma M_O = 0$

or, use computing equations $F_R = p_c \cdot A$ $y' = y_c + \frac{I_{xx}}{A \cdot y_c}$

Assumptions: static fluid; $\rho = \text{constant}$; p_{atm} on other side; door is in equilibrium

Instead of using either of these approaches, we note the following, using y as in the sketch

$$\Sigma M_O = 0 \quad W \cdot \frac{L}{2} \cdot \cos(\theta) = \int y \, dF$$

We also have $dF = p \cdot dA$ with $p = \rho \cdot g \cdot h = \rho \cdot g \cdot y \cdot \sin(\theta)$ (Gage pressure, since $p = p_{\text{atm}}$ on other side)

Hence $W = \frac{2}{L \cdot \cos(\theta)} \cdot \int y \cdot p \, dA = \frac{2}{L \cdot \cos(\theta)} \cdot \int y \cdot \rho \cdot g \cdot y \cdot \sin(\theta) \cdot w \, dy$

$$W = \frac{2}{L \cdot \cos(\theta)} \cdot \int y \cdot p \, dA = \frac{2 \cdot \rho \cdot g \cdot w \cdot \tan(\theta)}{L} \cdot \int_0^L y^2 \, dy = \frac{2}{3} \cdot \rho \cdot g \cdot w \cdot L^2 \cdot \tan(\theta)$$

Using given data $W = \frac{2}{3} \cdot 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2 \cdot \text{m} \times (3 \cdot \text{m})^2 \times \tan(30 \cdot \text{deg}) \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $W = 68 \cdot \text{kN}$

Problem 3.46

[Difficulty: 3]

3.46 A rectangular gate (width $w = 2$ m) is hinged as shown, with a stop on the lower edge. At what depth H will the gate tip?

Given: Gate geometry

Find: Depth H at which gate tips

Solution:

This is a problem with atmospheric pressure on both sides of the plate, so we can first determine the location of the center of pressure with respect to the free surface,

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} \quad \text{and} \quad I_{xx} = \frac{w \cdot L^3}{12} \quad \text{with} \quad y_c = H - \frac{L}{2}$$

where $L = 1$ m is the plate height and w is the plate width

Hence

$$y' = \left(H - \frac{L}{2} \right) + \frac{w \cdot L^3}{12 \cdot w \cdot L \cdot \left(H - \frac{L}{2} \right)} = \left(H - \frac{L}{2} \right) + \frac{L^2}{12 \cdot \left(H - \frac{L}{2} \right)}$$

But for equilibrium, the center of force must always be at or below the level of the hinge so that the stop can hold the gate in place. Hence we must have

$$y' > H - 0.45 \cdot \text{m}$$

Combining the two equations

$$\left(H - \frac{L}{2} \right) + \frac{L^2}{12 \cdot \left(H - \frac{L}{2} \right)} \geq H - 0.45 \cdot \text{m}$$

Solving for H

$$H \leq \frac{L}{2} + \frac{L^2}{12 \cdot \left(\frac{L}{2} - 0.45 \cdot \text{m} \right)} \quad H \leq \frac{1 \cdot \text{m}}{2} + \frac{(1 \cdot \text{m})^2}{12 \times \left(\frac{1 \cdot \text{m}}{2} - 0.45 \cdot \text{m} \right)} \quad H \leq 2.17 \cdot \text{m}$$

Problem 3.47

[Difficulty: 3]

3.47

Gates in the Poe Lock at Sault Ste. Marie, Michigan, close a channel $W = 34$ m wide, $L = 360$ m long, and $D = 10$ m deep. The geometry of one pair of gates is shown; each gate is hinged at the channel wall. When closed, the gate edges are forced together at the center of the channel by water pressure. Evaluate the force exerted by the water on gate A. Determine the magnitude and direction of the force components exerted by the gate on the hinge. (Neglect the weight of the gate.)

Given: Geometry of lock system

Find: Force on gate; reactions at hinge

Solution:

Basic equation $F_R = \int p \, dA$ $\frac{dp}{dh} = \rho \cdot g$

or, use computing equation $F_R = p_c \cdot A$

Assumptions: static fluid; $\rho = \text{constant}$; p_{atm} on other side

The force on each gate is the same as that on a rectangle of size

$$h = D = 10 \cdot \text{m} \quad \text{and} \quad w = \frac{W}{2 \cdot \cos(15 \cdot \text{deg})}$$

$$F_R = \int p \, dA = \int \rho \cdot g \cdot y \, dA \quad \text{but} \quad dA = w \cdot dy$$

Hence
$$F_R = \int_0^h \rho \cdot g \cdot y \cdot w \, dy = \frac{\rho \cdot g \cdot w \cdot h^2}{2}$$

Alternatively $F_R = p_c \cdot A$ and $F_R = p_c \cdot A = \rho \cdot g \cdot y_c \cdot A = \rho \cdot g \cdot \frac{h}{2} \cdot h \cdot w = \frac{\rho \cdot g \cdot w \cdot h^2}{2}$

Using given data
$$F_R = \frac{1}{2} \cdot 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times \frac{34 \cdot \text{m}}{2 \cdot \cos(15 \cdot \text{deg})} \times (10 \cdot \text{m})^2 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad F_R = 8.63 \cdot \text{MN}$$

For the force components R_x and R_y we do the following

$$\Sigma M_{\text{hinge}} = 0 = F_R \cdot \frac{w}{2} - F_n \cdot w \cdot \sin(15 \cdot \text{deg}) \quad F_n = \frac{F_R}{2 \cdot \sin(15 \cdot \text{deg})} \quad F_n = 16.7 \cdot \text{MN}$$

$$\Sigma F_x = 0 = F_R \cdot \cos(15 \cdot \text{deg}) - R_x = 0 \quad R_x = F_R \cdot \cos(15 \cdot \text{deg}) \quad R_x = 8.34 \cdot \text{MN}$$

$$\Sigma F_y = 0 = -R_y - F_R \cdot \sin(15 \cdot \text{deg}) + F_n = 0 \quad R_y = F_n - F_R \cdot \sin(15 \cdot \text{deg}) \quad R_y = 14.4 \cdot \text{MN}$$

$$R = (8.34 \cdot \text{MN}, 14.4 \cdot \text{MN})$$

$$R = 16.7 \cdot \text{MN}$$

Problem 3.48

(Difficulty: 2)

3.48 Calculate the minimum force P necessary to hold a uniform 12 ft square gate weighing 500 lbf closed on a tank of water under a pressure of 10 psi. Draw a free body of the gate as part of your solution.

Given: All the parameters are shown in the figure.

Find: The minimum force P to hold the system.

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure, force, and moments, with y measured from the surface of the liquid:

$$\frac{dp}{dy} = \rho g = \gamma$$

$$F_R = \int p dA$$

$$y' F_R = \int y p dA$$

A free body diagram of the gate is

The gage pressure of the air in the tank is:

$$p_{air} = 10 \text{ psi} = 1440 \frac{\text{lbf}}{\text{ft}^2}$$

This produces a uniform force on the gate of

$$F_1 = p_{air}A = 1440 \frac{\text{lbf}}{\text{ft}^2} \times (12 \text{ ft} \times 12 \text{ ft}) = 207360 \text{ lbf}$$

This pressure acts at the centroid of the area, which is the center of the gate. In addition, there is a force on the gate applied by water. This force is due to the pressure at the centroid of the area. The depth of the centroid is:

$$y_c = \frac{12 \text{ ft}}{2} \times \sin 45^\circ$$

The force is then

$$F_2 = \gamma h_c A = 62.4 \frac{\text{lbf}}{\text{ft}^3} \times \frac{12 \text{ ft}}{2} \times \sin 45^\circ \times 12 \text{ ft} \times 12 \text{ ft} = 38123 \text{ lbf}$$

The force F_2 acts two-thirds of the way down from the hinge, or $y' = 8 \text{ ft}$.

Take the moments about the hinge:

$$-F_B \frac{L}{2} \sin 45^\circ + F_1 \frac{L}{2} + F_2 \times 8 \text{ ft} - P \times 12 \text{ ft} = 0$$

Thus

$$P = \frac{-500 \text{ lbf} \times 6 \text{ ft} \times \sin 45^\circ + 207360 \text{ lbf} \times 6 \text{ ft} + 38123 \text{ lbf} \times 8 \text{ ft}}{12 \text{ ft}} = 128900 \text{ lbf}$$

Problem 3.49

(Difficulty: 2)

3.49 Calculate magnitude and location of the resultant force of water on this annular gate.

Given: All the parameters are shown in the figure.

Find: Resultant force of water on this annular gate.

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure, force, and moments, with y measured from the surface of the liquid:

$$\frac{dp}{dy} = \rho g = \gamma$$

$$F_R = \int p dA$$

$$y' F_R = \int y p dA$$

For the magnitude of the force we have:

$$F = \int_A p dA = \rho g h_c A$$

The pressure is determined at the location of the centroid of the area

$$h_c = 1 \text{ m} + 1.5 \text{ m} = 2.5 \text{ m}$$

$$A = \frac{\pi}{4} (D_2^2 - D_1^2) = \frac{\pi}{4} ((3 \text{ m})^2 - (1.5 \text{ m})^2) = 5.3014 \text{ m}^2$$

$$F = 999 \frac{\text{kg}}{\text{m}^3} \times 9.81 \frac{\text{m}}{\text{s}^2} \times 2.5 \text{ m} \times 5.3014 \text{ m}^2 = 129900 \text{ N} = 129.9 \text{ kN}$$

The y axis is in the vertical direction. For the location of the force, we have:

$$y' = y_c + \frac{I_{\hat{x}\hat{x}}}{Ay_c}$$

Where:

$$y_c = 2.5 \text{ m}$$

$$I_{\hat{x}\hat{x}} = \frac{\pi(D_2^4 - D_1^4)}{64} = \frac{\pi}{64} \times ((3 \text{ m})^4 - (1.5 \text{ m})^4) = 3.7276 \text{ m}^4$$

$$y' = y_c + \frac{I_{\hat{x}\hat{x}}}{Ay_c} = 2.5 \text{ m} + \frac{3.7276 \text{ m}^4}{2.5 \text{ m} \times 5.3014 \text{ m}^2} = 2.78 \text{ m}$$

So the force acts on the depth of $y' = 2.78 \text{ m}$.

Problem 3.50

(Difficulty: 2)

3.50 A vertical rectangular gate 2.4 m wide and 2.7 m high is subjected to water pressure on one side, the water surface being at the top of the gate. The gate is hinged at the bottom and is held by a horizontal chain at the top. What is the tension in the chain?

Given: The gate wide: $w = 2.4\text{ m}$. Height of the gate: $h = 2.7\text{ m}$.

Find: The tension F_c in the chain.

Assumptions: Fluid is static and incompressible

Solution: Apply the hydrostatic relations for pressure, force, and moments, with y measured from the surface of the liquid:

$$\frac{dp}{dy} = \rho g = \gamma$$

$$F_R = \int p dA$$

$$y' F_R = \int y p dA$$

For the magnitude of the force we have:

$$F = \int_A p dA = \rho g h_c A$$

Where h_c is the depth at the centroid

$$h_c = \frac{2.7\text{ m}}{2} = 1.35\text{ m}$$

$$A = wh = 2.4\text{ m} \times 2.7\text{ m} = 6.48\text{ m}^2$$

$$F = 999 \frac{kg}{m^3} \times 9.81 \frac{m}{s^2} \times 1.35 m \times 6.48 m^2 = 85.7 kN$$

The y axis is in the vertical direction. For the location of the force, we have:

$$h_p = \frac{2}{3} \times 2.7 m = 1.8 m$$

Taking the momentum about the hinge:

$$F(h - h_p) - F_c h = 0$$

$$F_c = F \frac{(h - h_p)}{h} = 85.7 kN \times \frac{0.9 m}{2.7 m} = 28.6 kN$$

Problem 3.51

[Difficulty: 4]

3.51 A window in the shape of an isosceles triangle and hinged at the top is placed in the vertical wall of a form that contains liquid concrete. Determine the minimum force that must be applied at point D to keep the window closed for the configuration of form and concrete shown. Plot the results over the range of concrete depth $0 \leq c \leq a$

Given: Window, in shape of isosceles triangle and hinged at the top is located in the vertical wall of a form that contains concrete.

$$a = 0.4 \text{ m} \quad b = 0.3 \text{ m} \quad c = 0.25 \text{ m} \quad SG_c = 2.5$$

Find: The minimum force applied at D needed to keep the window closed.
Plot the results over the range of concrete depth between 0 and a .

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards})$$

$$F_R = \int p \, dA \quad (\text{Hydrostatic Force on door})$$

$$y' \cdot F_R = \int y \cdot p \, dA \quad (\text{First moment of force})$$

$$\Sigma M = 0 \quad (\text{Rotational equilibrium})$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts at free surface and on the outside of the window.

Integrating the pressure equation yields: $p = \rho \cdot g \cdot (h - d)$ for $h > d$

$$p = 0 \quad \text{for } h < d$$

$$\text{where} \quad d = a - c \quad d = 0.15 \text{ m}$$

Summing moments around the hinge: $-F_D \cdot a + \int h \cdot p \, dA = 0$

$$F_D = \frac{1}{a} \cdot \int h \cdot p \, dA = \frac{1}{a} \cdot \int_d^a h \cdot \rho \cdot g \cdot (h - d) \cdot w \, dh = \frac{\rho \cdot g}{a} \cdot \int_d^a h \cdot (h - d) \cdot w \, dh$$

From the law of similar triangles: $\frac{w}{b} = \frac{a - h}{a}$ Therefore: $w = \frac{b}{a} (a - h)$

Into the expression for the force at D:
$$F_D = \frac{\rho \cdot g}{a} \cdot \int_d^a \frac{b}{a} \cdot h \cdot (h - d) \cdot (a - h) dh = \frac{\rho \cdot g \cdot b}{a^2} \cdot \int_d^a [-h^3 + (a + d) \cdot h^2 - a \cdot d \cdot h] dh$$

Evaluating this integral we get:

$$F_D = \frac{\rho \cdot g \cdot b}{a^2} \cdot \left[-\frac{(a^4 - d^4)}{4} + \frac{(a + d) \cdot (a^3 - d^3)}{3} - \frac{a \cdot d \cdot (a^2 - d^2)}{2} \right] \quad \text{and after collecting terms:}$$

$$F_D = \rho \cdot g \cdot b \cdot a^2 \cdot \left[-\frac{1}{4} \cdot \left[1 - \left(\frac{d}{a} \right)^4 \right] + \frac{1}{3} \cdot \left(1 + \frac{d}{a} \right) \cdot \left[1 - \left(\frac{d}{a} \right)^3 \right] - \frac{1}{2} \cdot \frac{d}{a} \cdot \left[1 - \left(\frac{d}{a} \right)^2 \right] \right] \quad (1)$$

The density of the concrete is: $\rho = 2.5 \times 1000 \cdot \frac{\text{kg}}{\text{m}^3} \quad \rho = 2.5 \times 10^3 \frac{\text{kg}}{\text{m}^3} \quad \frac{d}{a} = \frac{0.15}{0.4} = 0.375$

Substituting in values for the force at D:

$$F_D = 2.5 \times 10^3 \cdot \frac{\text{kg}}{\text{m}^3} \cdot 9.81 \cdot \frac{\text{m}}{\text{s}^2} \cdot 0.3 \cdot \text{m} \cdot (0.4 \cdot \text{m})^2 \cdot \left[-\frac{1}{4} \cdot \left[1 - (0.375)^4 \right] + \frac{1}{3} \cdot (1 + 0.375) \cdot \left[1 - (0.375)^3 \right] - \frac{0.375}{2} \cdot \left[1 - (0.375)^2 \right] \right] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

To plot the results for different values of c/a , we use Eq. (1) and remember that $d = a - c$ $F_D = 32.9 \text{ N}$

Therefore, it follows that $\frac{d}{a} = 1 - \frac{c}{a}$ In addition, we can maximize the force by the maximum force (when $c = a$ or $d = 0$):

$$F_{\max} = \rho \cdot g \cdot b \cdot a^2 \cdot \left(-\frac{1}{4} + \frac{1}{3} \right) = \frac{\rho \cdot g \cdot b \cdot a^2}{12} \quad \text{and so} \quad \frac{F_D}{F_{\max}} = 12 \cdot \left[-\frac{1}{4} \cdot \left[1 - \left(\frac{d}{a} \right)^4 \right] + \frac{1}{3} \cdot \left(1 + \frac{d}{a} \right) \cdot \left[1 - \left(\frac{d}{a} \right)^3 \right] - \frac{1}{2} \cdot \frac{d}{a} \cdot \left[1 - \left(\frac{d}{a} \right)^2 \right] \right]$$

Problem 3.52

[Difficulty: 2]

3.52 A large open tank contains water and is connected to a 6-ft-diameter conduit as shown. A circular plug is used to seal the conduit. Determine the magnitude, direction, and location of the force of the water on the plug.

Given: Plug is used to seal a conduit. $\gamma = 62.4 \cdot \frac{\text{lb}}{\text{ft}^3}$

Find: Magnitude, direction and location of the force of water on the plug.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \gamma \quad (\text{Hydrostatic Pressure - } y \text{ is positive downwards})$$

$$F_R = p_c \cdot A \quad (\text{Hydrostatic Force})$$

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} \quad (\text{Location of line of action})$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts on the outside of the plug.

Integrating the hydrostatic pressure equation: $p = \gamma \cdot h$ $F_R = p_c \cdot A = \gamma \cdot h_c \cdot \frac{\pi}{4} \cdot D^2$

$$F_R = 62.4 \cdot \frac{\text{lb}}{\text{ft}^3} \times 12 \cdot \text{ft} \times \frac{\pi}{4} \times (6 \cdot \text{ft})^2 \quad F_R = 2.12 \times 10^4 \cdot \text{lb}$$

For a circular area: $I_{xx} = \frac{\pi}{64} \cdot D^4$ Therefore: $y' = y_c + \frac{\frac{\pi}{64} \cdot D^4}{\frac{\pi}{4} \cdot D^2 \cdot y_c} = y_c + \frac{D^2}{16 \cdot y_c}$ $y' = 12 \cdot \text{ft} + \frac{(6 \cdot \text{ft})^2}{16 \times 12 \cdot \text{ft}}$

$$y' = 12.19 \cdot \text{ft}$$

The force of water is to the right and perpendicular to the plug.

Problem 3.53

[Difficulty: 2]

3.53 The circular access port in the side of a water standpipe has a diameter of 0.6 m and is held in place by eight bolts evenly spaced around the circumference. If the standpipe diameter is 7 m and the center of the port is located 12 m below the free surface of the water, determine (a) the total force on the port and (b) the appropriate bolt diameter.

Given: Circular access port of known diameter in side of water standpipe of known diameter. Port is held in place by eight bolts evenly spaced around the circumference of the port.
Center of the port is located at a know distance below the free surface of the water.
 $d = 0.6 \cdot \text{m}$ $D = 7 \cdot \text{m}$ $L = 12 \cdot \text{m}$

Find: (a) Total force on the port
(b) Appropriate bolt diameter

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $\frac{dp}{dh} = \rho \cdot g$ (Hydrostatic Pressure - y is positive downwards)
 $F_R = p_C \cdot A$ (Hydrostatic Force)
 $\sigma = \frac{F}{A}$ (Normal Stress in bolt)

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Force is distributed evenly over all bolts
(4) Appropriate working stress in bolts is 100 MPa
(5) Atmospheric pressure acts at free surface of water and on outside of port.

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

The resultant force on the port is: $F_R = p_C \cdot A = \rho \cdot g \cdot L \cdot \frac{\pi}{4} \cdot d^2$ $F_R = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 12 \cdot \text{m} \times \frac{\pi}{4} \times (0.6 \cdot \text{m})^2 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$

$$F_R = 33.3 \cdot \text{kN}$$

To find the bolt diameter we consider: $\sigma = \frac{F_R}{A}$ where A is the area of all of the bolts: $A = 8 \times \frac{\pi}{4} \cdot d_b^2 = 2 \cdot \pi \cdot d_b^2$

Therefore: $2 \cdot \pi \cdot d_b^2 = \frac{F_R}{\sigma}$ Solving for the bolt diameter we get: $d_b = \left(\frac{F_R}{2 \cdot \pi \cdot \sigma} \right)^{\frac{1}{2}}$

$$d_b = \left(\frac{1}{2 \times \pi} \times 33.3 \times 10^3 \cdot \text{N} \times \frac{1}{100 \times 10^6 \cdot \frac{\text{N}}{\text{m}^2}} \right)^{\frac{1}{2}} \times \frac{10^3 \cdot \text{mm}}{\text{m}} \quad d_b = 7.28 \cdot \text{mm}$$

Problem 3.54

[Difficulty: 3]

3.54 The gate AOC shown is 6 ft wide and is hinged along O . Neglecting the weight of the gate, determine the force in bar AB . The gate is sealed at C .

Given: Gate AOC , hinged along O , has known width;
Weight of gate may be neglected. Gate is sealed at C .

$$b = 6\text{ ft}$$

Find: Force in bar AB

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure} - h \text{ is positive downwards})$$

$$F_R = p_c \cdot A \quad (\text{Hydrostatic Force})$$

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} \quad (\text{Location of line of action})$$

$$\Sigma M_z = 0 \quad (\text{Rotational equilibrium})$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts at free surface of water and on outside of gate
- (4) No resisting moment in hinge at O
- (5) No vertical resisting force at C

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

The free body diagram of the gate is shown here:

F_1 is the resultant of the distributed force on AO

F_2 is the resultant of the distributed force on OC

F_{AB} is the force of the bar

C_x is the sealing force at C

First find the force on AO : $F_1 = p_c \cdot A_1 = \rho \cdot g \cdot h_{c1} \cdot b \cdot L_1$

$$F_1 = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 6 \cdot \text{ft} \times 6 \cdot \text{ft} \times 12 \cdot \text{ft} \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slugft}}$$

$$F_1 = 27.0 \cdot \text{kip}$$

$$h'_1 = h_{c1} + \frac{I_{xx}}{A \cdot h_{c1}} = h_{c1} + \frac{b \cdot L_1^3}{12 \cdot b \cdot L_1 \cdot h_{c1}} = h_{c1} + \frac{L_1^2}{12 \cdot h_{c1}} \quad h'_1 = 6 \cdot \text{ft} + \frac{(12 \cdot \text{ft})^2}{12 \times 6 \cdot \text{ft}} \quad h'_1 = 8 \cdot \text{ft}$$

Next find the force on OC: $F_2 = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 12 \cdot \text{ft} \times 6 \cdot \text{ft} \times 6 \cdot \text{ft} \times \frac{\text{lb} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}} \quad F_2 = 27.0 \cdot \text{kip}$

Since the pressure is uniform over OC, the force acts at the centroid of OC, i.e., $x'_2 = 3 \cdot \text{ft}$

Summing moments about the hinge gives: $F_{AB} \cdot (L_1 + L_3) - F_1 \cdot (L_1 - h'_1) + F_2 \cdot x'_2 = 0$

Solving for the force in the bar: $F_{AB} = \frac{F_1 \cdot (L_1 - h'_1) - F_2 \cdot x'_2}{L_1 + L_3}$

Substituting in values: $F_{AB} = \frac{1}{12 \cdot \text{ft} + 3 \cdot \text{ft}} \cdot [27.0 \times 10^3 \cdot \text{lb} \cdot \text{ft} \times (12 \cdot \text{ft} - 8 \cdot \text{ft}) - 27.0 \times 10^3 \cdot \text{lb} \cdot \text{ft} \times 3 \cdot \text{ft}]$

$$F_{AB} = 1800 \cdot \text{lb} \cdot \text{ft}$$

Thus bar AB is in compression

Problem 3.55

[Difficulty: 3]

3.55 The gate shown is hinged at H . The gate is 3 m wide normal to the plane of the diagram. Calculate the force required at A to hold the gate closed.

Given: Geometry of gate

Find: Force at A to hold gate closed

Solution:

Basic equation $\frac{dp}{dh} = \rho \cdot g$ $\Sigma M_Z = 0$

Computing equations $F_R = p_c \cdot A$ $y' = y_c + \frac{I_{xx}}{A \cdot y_c}$ $I_{xx} = \frac{w \cdot L^3}{12}$

Assumptions: Static fluid; $\rho = \text{constant}$; p_{atm} on other side; no friction in hinge

For incompressible fluid $p = \rho \cdot g \cdot h$ where p is gage pressure and h is measured downwards

The hydrostatic force on the gate is that on a rectangle of size L and width w .

Hence

$$F_R = p_c \cdot A = \rho \cdot g \cdot h_c \cdot A = \rho \cdot g \cdot \left(D + \frac{L}{2} \cdot \sin(30^\circ) \right) \cdot L \cdot w$$

$$F_R = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times \left(1.5 + \frac{3}{2} \sin(30^\circ) \right) \cdot \text{m} \times 3 \cdot \text{m} \times 3 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad F_R = 199 \cdot \text{kN}$$

The location of this force is given by $y' = y_c + \frac{I_{xx}}{A \cdot y_c}$ where y' and y_c are measured along the plane of the gate to the free surface

$$y_c = \frac{D}{\sin(30^\circ)} + \frac{L}{2} \quad y_c = \frac{1.5 \cdot \text{m}}{\sin(30^\circ)} + \frac{3 \cdot \text{m}}{2} \quad y_c = 4.5 \text{ m}$$

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} = y_c + \frac{w \cdot L^3}{12} \cdot \frac{1}{w \cdot L} \cdot \frac{1}{y_c} = y_c + \frac{L^2}{12 \cdot y_c} = 4.5 \cdot \text{m} + \frac{(3 \cdot \text{m})^2}{12 \cdot 4.5 \cdot \text{m}} \quad y' = 4.67 \text{ m}$$

Taking moments about the hinge $\Sigma M_H = 0 = F_R \cdot \left(y' - \frac{D}{\sin(30^\circ)} \right) - F_A \cdot L$

$$F_A = F_R \cdot \frac{\left(y' - \frac{D}{\sin(30^\circ)} \right)}{L} \quad F_A = 199 \cdot \text{kN} \cdot \frac{\left(4.67 - \frac{1.5}{\sin(30^\circ)} \right)}{3} \quad F_A = 111 \cdot \text{kN}$$

Problem 3.56

[Difficulty: 4]

3.56

A solid concrete dam is to be built to hold back a depth D of water. For ease of construction the walls of the dam must be planar. Your supervisor asks you to consider the following dam cross-sections: a rectangle, a right triangle with the hypotenuse in contact with the water, and a right triangle with the vertical in contact with the water. She wishes you to determine which of these would require the least amount of concrete. What will your report say? You decide to look at one more possibility: a nonright triangle, as shown. Develop and plot an expression for the cross-section area A as a function of α , and find the minimum cross-sectional area.

Given: Various dam cross-sections

Find: Which requires the least concrete; plot cross-section area A as a function of α

Solution:

For each case, the dam width b has to be large enough so that the weight of the dam exerts enough moment to balance the moment due to fluid hydrostatic force(s). By doing a moment balance this value of b can be found

a) Rectangular dam

Straightforward application of the computing equations of Section 3-5 yields

$$F_H = p_c \cdot A = \rho \cdot g \cdot \frac{D}{2} \cdot w \cdot D = \frac{1}{2} \cdot \rho \cdot g \cdot D^2 \cdot w$$

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} = \frac{D}{2} + \frac{w \cdot D^3}{12 \cdot w \cdot D \cdot \frac{D}{2}} = \frac{2}{3} \cdot D$$

so $y = D - y' = \frac{D}{3}$

Also $m = \rho_{\text{cement}} \cdot g \cdot b \cdot D \cdot w = SG \cdot \rho \cdot g \cdot b \cdot D \cdot w$

Taking moments about O

$$\sum M_{O.} = 0 = -F_H \cdot y + \frac{b}{2} \cdot m \cdot g$$

so

$$\left(\frac{1}{2} \cdot \rho \cdot g \cdot D^2 \cdot w \right) \cdot \frac{D}{3} = \frac{b}{2} \cdot (SG \cdot \rho \cdot g \cdot b \cdot D \cdot w)$$

Solving for b

$$b = \frac{D}{\sqrt{3 \cdot SG}}$$

The minimum rectangular cross-section area is $A = b \cdot D = \frac{D^2}{\sqrt{3 \cdot SG}}$

For concrete, from Table A.1, $SG = 2.4$, so $A = \frac{D^2}{\sqrt{3 \cdot SG}} = \frac{D^2}{\sqrt{3 \times 2.4}}$

$$A = 0.373 \cdot D^2$$

b) Triangular dams

Instead of analysing right-triangles, a general analysis is made, at the end of which right triangles are analysed as special cases by setting $\alpha = 0$ or 1.

Straightforward application of the computing equations of Section 3-5 yields

$$F_H = p_c \cdot A = \rho \cdot g \cdot \frac{D}{2} \cdot w \cdot D = \frac{1}{2} \cdot \rho \cdot g \cdot D^2 \cdot w$$

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} = \frac{D}{2} + \frac{w \cdot D^3}{12 \cdot w \cdot D \cdot \frac{D}{2}} = \frac{2}{3} \cdot D$$

so
$$y = D - y' = \frac{D}{3}$$

Also
$$F_V = \rho \cdot V \cdot g = \rho \cdot g \cdot \frac{\alpha \cdot b \cdot D}{2} \cdot w = \frac{1}{2} \cdot \rho \cdot g \cdot \alpha \cdot b \cdot D \cdot w \quad x = (b - \alpha \cdot b) + \frac{2}{3} \cdot \alpha \cdot b = b \cdot \left(1 - \frac{\alpha}{3}\right)$$

For the two triangular masses

$$m_1 = \frac{1}{2} \cdot SG \cdot \rho \cdot g \cdot \alpha \cdot b \cdot D \cdot w \quad x_1 = (b - \alpha \cdot b) + \frac{1}{3} \cdot \alpha \cdot b = b \cdot \left(1 - \frac{2 \cdot \alpha}{3}\right)$$

$$m_2 = \frac{1}{2} \cdot SG \cdot \rho \cdot g \cdot (1 - \alpha) \cdot b \cdot D \cdot w \quad x_2 = \frac{2}{3} \cdot b \cdot (1 - \alpha)$$

Taking moments about O

$$\sum M_O = 0 = -F_H \cdot y + F_V \cdot x + m_1 \cdot g \cdot x_1 + m_2 \cdot g \cdot x_2$$

so
$$-\left(\frac{1}{2} \cdot \rho \cdot g \cdot D^2 \cdot w\right) \cdot \frac{D}{3} + \left(\frac{1}{2} \cdot \rho \cdot g \cdot \alpha \cdot b \cdot D \cdot w\right) \cdot b \cdot \left(1 - \frac{\alpha}{3}\right) + \left(\frac{1}{2} \cdot SG \cdot \rho \cdot g \cdot \alpha \cdot b \cdot D \cdot w\right) \cdot b \cdot \left(1 - \frac{2 \cdot \alpha}{3}\right) + \left[\frac{1}{2} \cdot SG \cdot \rho \cdot g \cdot (1 - \alpha) \cdot b \cdot D \cdot w\right] \cdot \frac{2}{3} \cdot b \cdot (1 - \alpha) = 0$$

Solving for b
$$b = \frac{D}{\sqrt{(3 \cdot \alpha - \alpha^2) + SG \cdot (2 - \alpha)}}$$

For a right triangle with the hypotenuse in contact with the water, $\alpha = 1$, and

$$b = \frac{D}{\sqrt{3 - 1 + SG}} = \frac{D}{\sqrt{3 - 1 + 2.4}} \quad b = 0.477 \cdot D$$

The cross-section area is
$$A = \frac{b \cdot D}{2} = 0.238 \cdot D^2 \quad A = 0.238 \cdot D^2$$

For a right triangle with the vertical in contact with the water, $\alpha = 0$, and

$$b = \frac{D}{\sqrt{2 \cdot SG}} = \frac{D}{\sqrt{2 \cdot 2.4}}$$

$$b = 0.456 \cdot D$$

The cross-section area is

$$A = \frac{b \cdot D}{2} = 0.228 \cdot D^2$$

$$A = 0.228 \cdot D^2$$

For a general triangle

$$A = \frac{b \cdot D}{2} = \frac{D^2}{2 \cdot \sqrt{(3 \cdot \alpha - \alpha^2) + SG \cdot (2 - \alpha)}}$$

$$A = \frac{D^2}{2 \cdot \sqrt{(3 \cdot \alpha - \alpha^2) + 2.4 \cdot (2 - \alpha)}}$$

The final result is

$$A = \frac{D^2}{2 \cdot \sqrt{4.8 + 0.6 \cdot \alpha - \alpha^2}}$$

The dimensionless area, A/D^2 , is plotted

<i>Alpha</i>	<i>A/D²</i>
0.0	0.2282
0.1	0.2270
0.2	0.2263
0.3	0.2261
0.4	0.2263
0.5	0.2270
0.6	0.2282
0.7	0.2299
0.8	0.2321
0.9	0.2349
1.0	0.2384

Solver can be used to find the minimum area

<i>Alpha</i>	<i>A/D²</i>
0.300	0.2261

From the Excel workbook, the minimum area occurs at $\alpha = 0.3$

$$A_{\min} = \frac{D^2}{2 \cdot \sqrt{4.8 + 0.6 \times 0.3 - 0.3^2}}$$

$$A = 0.226 \cdot D^2$$

The final results are that a triangular cross-section with $\alpha = 0.3$ uses the least concrete; the next best is a right triangle with the vertical in contact with the water; next is the right triangle with the hypotenuse in contact with the water; and the cross-section requiring the most concrete is the rectangular cross-section.

Problem 3.57

[Difficulty: 2]

3.57 For the dam shown, what is the vertical force of the water on the dam?

Given: Geometry of dam

Find: Vertical force on dam

Assumptions: (1) water is static and incompressible
(2) since we are asked for the force of the water, all pressures will be written as gage

Solution:

Basic equation: $\frac{dp}{dh} = \rho \cdot g$

For incompressible fluid $p = \rho \cdot g \cdot h$ where p is gage pressure and h is measured downwards from the free surface

The force on each horizontal section (depth d and width w) is

$$F = p \cdot A = \rho \cdot g \cdot h \cdot d \cdot w \quad (\text{Note that } d \text{ and } w \text{ will change in terms of } x \text{ and } y \text{ for each section of the dam!})$$

Hence the total force is (allowing for the fact that some faces experience an upwards (negative) force)

$$F_T = p \cdot A = \Sigma \rho \cdot g \cdot h \cdot d \cdot w = \rho \cdot g \cdot d \cdot \Sigma h \cdot w$$

Starting with the top and working downwards

$$F_T = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 3 \cdot \text{ft} \times [(3 \cdot \text{ft} \times 12 \cdot \text{ft}) + (3 \cdot \text{ft} \times 6 \cdot \text{ft}) - (9 \cdot \text{ft} \times 6 \cdot \text{ft}) - (12 \cdot \text{ft} \times 12 \cdot \text{ft})] \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}}$$

$$F_T = -2.70 \times 10^4 \cdot \text{lbf} \quad \text{The negative sign indicates a net upwards force (it's actually a buoyancy effect on the three middle sections)}$$

Problem 3.58

[Difficulty: 3]

3.58 The parabolic gate shown is 2 m wide and pivoted at O ; $c = 0.25 \text{ m}^{-1}$, $D = 2 \text{ m}$, and $H = 3 \text{ m}$. Determine (a) the magnitude and line of action of the vertical force on the gate due to the water, (b) the horizontal force applied at A required to maintain the gate in equilibrium, and (c) the vertical force applied at A required to maintain the gate in equilibrium.

Given: Parabolic gate, hinged at O has a constant width.

$$b = 2 \cdot \text{m} \quad c = 0.25 \cdot \text{m}^{-1} \quad D = 2 \cdot \text{m} \quad H = 3 \cdot \text{m}$$

Find: (a) Magnitude and line of action of the vertical force on the gate due to water
(b) Horizontal force applied at A required to maintain equilibrium
(c) Vertical force applied at A required to maintain equilibrium

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards})$$

$$\Sigma M_Z = 0 \quad (\text{Rotational equilibrium})$$

$$F_V = \int p \, dA_y \quad (\text{Vertical Hydrostatic Force})$$

$$x' \cdot F_V = \int x \, dF_V \quad (\text{Location of line of action})$$

$$F_H = p_c \cdot A \quad (\text{Horizontal Hydrostatic Force})$$

$$h' = h_c + \frac{I_{xx}}{A \cdot h_c} \quad (\text{Location of line of action})$$

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Atmospheric pressure acts at free surface of water and on outside of gate

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

(a) The magnitude and line of action of the vertical component of hydrostatic force:

$$F_V = \int p \, dA_y = \int_0^{\sqrt{\frac{D}{c}}} \rho \cdot g \cdot h \cdot b \, dx = \int_0^{\sqrt{\frac{D}{c}}} \rho \cdot g \cdot (D - y) b \, dx = \int_0^{\sqrt{\frac{D}{c}}} \rho \cdot g \cdot (D - c \cdot x^2) b \, dx = \rho \cdot g \cdot b \cdot \int_0^{\sqrt{\frac{D}{c}}} (D - c \cdot x^2) \, dx$$

$$\text{Evaluating the integral: } F_V = \rho \cdot g \cdot b \cdot \left(\frac{D}{\frac{1}{c^{\frac{1}{2}}}} - \frac{1}{3} \cdot \frac{D^{\frac{3}{2}}}{\frac{1}{c^{\frac{1}{2}}}} \right) = \frac{2 \cdot \rho \cdot g \cdot b}{3} \cdot \frac{D^{\frac{3}{2}}}{\frac{1}{c^{\frac{1}{2}}}} \quad (1)$$

Substituting values: $F_V = \frac{2}{3} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2 \cdot \text{m} \times (2 \cdot \text{m})^{\frac{3}{2}} \times \left(\frac{1}{0.25} \cdot \text{m} \right)^{\frac{1}{2}} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $F_V = 73.9 \cdot \text{kN}$

To find the line of action of this force: $x' \cdot F_V = \int x \, dF_V$ Therefore, $x' = \frac{1}{F_V} \cdot \int x \, dF_V = \frac{1}{F_V} \cdot \int x \cdot p \, dA_y$

Using the derivation for the force: $x' = \frac{1}{F_V} \cdot \int_0^{\sqrt{\frac{D}{c}}} x \cdot \rho \cdot g \cdot (D - c \cdot x^2) \cdot b \, dx = \frac{\rho \cdot g \cdot b}{F_V} \cdot \int_0^{\sqrt{\frac{D}{c}}} (D \cdot x - c \cdot x^3) \, dx$

Evaluating the integral: $x' = \frac{\rho \cdot g \cdot b}{F_V} \cdot \left[\frac{D}{2} \cdot \frac{D}{c} - \frac{c}{4} \cdot \left(\frac{D}{c} \right)^2 \right] = \frac{\rho \cdot g \cdot b}{F_V} \cdot \frac{D^2}{4 \cdot c}$ Now substituting values into this equation:

$x' = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2 \cdot \text{m} \times \frac{1}{73.9 \times 10^3 \cdot \text{N}} \cdot \frac{1}{4} \times (2 \cdot \text{m})^2 \times \frac{1}{0.25} \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $x' = 1.061 \text{ m}$

To find the required force at A for equilibrium, we need to find the horizontal force of the water on the gate and its line of action as well. Once this force is known we take moments about the hinge (point O).

$F_H = p_c \cdot A = \rho \cdot g \cdot h_c \cdot b \cdot D = \rho \cdot g \cdot \frac{D}{2} \cdot b \cdot D = \rho \cdot g \cdot b \cdot \frac{D^2}{2}$ since $h_c = \frac{D}{2}$ Therefore the horizontal force is:

$F_H = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 2 \cdot \text{m} \times \frac{(2 \cdot \text{m})^2}{2} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $F_H = 39.2 \cdot \text{kN}$

To calculate the line of action of this force:

$h' = h_c + \frac{I_{xx}}{A \cdot h_c} = \frac{D}{2} + \frac{b \cdot D^3}{12 \cdot b \cdot D} \cdot \frac{1}{D} = \frac{D}{2} + \frac{D}{6} = \frac{2}{3} \cdot D$ $h' = \frac{2}{3} \cdot 2 \cdot \text{m}$ $h' = 1.333 \text{ m}$

Now we have information to solve parts (b) and (c):

(b) Horizontal force applied at A for equilibrium: take moments about O:

$F_A \cdot H - F_V \cdot x' - F_H \cdot (D - h') = 0$ Solving for F_A $F_A = \frac{F_V \cdot x' + F_H \cdot (D - h')}{H}$

$F_A = \frac{1}{3} \cdot \frac{1}{\text{m}} \times [73.9 \cdot \text{kN} \times 1.061 \cdot \text{m} + 39.2 \cdot \text{kN} \times (2 \cdot \text{m} - 1.333 \cdot \text{m})]$ $F_A = 34.9 \cdot \text{kN}$

(c) Vertical force applied at A for equilibrium: take moments about O:

$F_A \cdot L - F_V \cdot x' - F_H \cdot (D - h') = 0$ Solving for F_A $F_A = \frac{F_V \cdot x' + F_H \cdot (D - h')}{L}$

L is the value of x at y = H. Therefore: $L = \sqrt{\frac{H}{c}}$ $L = \sqrt{3 \cdot \text{m} \times \frac{1}{0.25} \cdot \text{m}}$ $L = 3.464 \text{ m}$

$F_A = \frac{1}{3.464} \cdot \frac{1}{\text{m}} \times [73.9 \cdot \text{kN} \times 1.061 \cdot \text{m} + 39.2 \cdot \text{kN} \times (2 \cdot \text{m} - 1.333 \cdot \text{m})]$ $F_A = 30.2 \cdot \text{kN}$

Problem 3.59

[Difficulty: 2]

3.59 An open tank is filled with water to the depth indicated. Atmospheric pressure acts on all outer surfaces of the tank. Determine the magnitude and line of action of the vertical component of the force of the water on the curved part of the tank bottom.

Given: Open tank as shown. Width of curved surface $b = 10 \cdot \text{ft}$

Find: (a) Magnitude of the vertical force component on the curved surface
(b) Line of action of the vertical component of the force

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \gamma \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards})$$

$$F_v = - \int p \, dA_y \quad (\text{Vertical Hydrostatic Force})$$

$$x' \cdot F_v = \int x \, dF_v \quad (\text{Moment of vertical force})$$

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Atmospheric pressure acts at free surface of water and on outside of wall

Integrating the hydrostatic pressure equation: $p = \gamma \cdot h$ We can define along the surface $h = L - (R^2 - x^2)^{\frac{1}{2}}$

We also define the incremental area on the curved surface as: $dA_y = b \cdot dx$ Substituting these into the force equation we get:

$$F_v = - \int p \, dA_y = - \int_0^R \gamma \cdot \left[L - (R^2 - x^2)^{\frac{1}{2}} \right] \cdot b \, dx = - \gamma \cdot b \cdot \int_0^R (L - \sqrt{R^2 - x^2}) \, dx = - \gamma \cdot b \cdot R \cdot \left(L - R \cdot \frac{\pi}{4} \right)$$

$$F_v = - \left[62.4 \cdot \frac{\text{lb}}{\text{ft}^3} \times 10 \cdot \text{ft} \times 4 \cdot \text{ft} \times \left(10 \cdot \text{ft} - 4 \cdot \text{ft} \times \frac{\pi}{4} \right) \right] \quad F_v = -17.12 \times 10^3 \cdot \text{lb} \quad (\text{negative indicates downward})$$

To find the line of action of the force: $x' \cdot F_v = \int x \, dF_v$ where $dF_v = -\gamma \cdot b \cdot (L - \sqrt{R^2 - x^2}) \cdot dx$

$$\text{Therefore: } x' = \frac{x' \cdot F_v}{F_v} = \frac{1}{\gamma \cdot b \cdot R \cdot \left(L - R \cdot \frac{\pi}{4} \right)} \cdot \int_0^R x \cdot \gamma \cdot b \cdot (L - \sqrt{R^2 - x^2}) \, dx = \frac{1}{R \cdot \left(L - R \cdot \frac{\pi}{4} \right)} \cdot \int_0^R (L \cdot x - x \cdot \sqrt{R^2 - x^2}) \, dx$$

$$\text{Evaluating the integral: } x' = \frac{4}{R \cdot (4 \cdot L - \pi \cdot R)} \cdot \left(\frac{1}{2} \cdot L \cdot R^2 - \frac{1}{3} \cdot R^3 \right) = \frac{4 \cdot R^2}{R \cdot (4 \cdot L - \pi \cdot R)} \cdot \left(\frac{L}{2} - \frac{R}{3} \right) = \frac{4 \cdot R}{4 \cdot L - \pi \cdot R} \cdot \left(\frac{L}{2} - \frac{R}{3} \right)$$

$$\text{Substituting known values: } x' = \frac{4 \cdot 4 \cdot \text{ft}}{4 \cdot 10 \cdot \text{ft} - \pi \cdot 4 \cdot \text{ft}} \cdot \left(\frac{10 \cdot \text{ft}}{2} - \frac{4 \cdot \text{ft}}{3} \right) \quad x' = 2.14 \cdot \text{ft}$$

Problem 3.60

[Difficulty: 3]

3.60 A dam is to be constructed using the cross-section shown. Assume the dam width is $w = 160$ ft. For water height $H = 9$ ft, calculate the magnitude and line of action of the vertical force of water on the dam face. Is it possible for water forces to overturn this dam? Under what circumstances will this happen?

Given: Dam with cross-section shown. Width of dam
b = 160·ft

Find:

- Magnitude and line of action of the vertical force component on the dam
- If it is possible for the water to overturn dam

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $\frac{dp}{dh} = \rho \cdot g$ (Hydrostatic Pressure - h is positive downwards from free surface)

$$F_v = \int p \, dA_y \quad (\text{Vertical Hydrostatic Force})$$

$$F_H = p_c \cdot A \quad \text{(Horizontal Hydrostatic Force)}$$

$$x' \cdot F_v = \int x \, dF_v \quad (\text{Moment of vertical force})$$

$$h' = h_c + \frac{I_{xx}}{h_c \cdot A} \quad (\text{Line of action of vertical force})$$

$$\Sigma M_z = 0 \quad \text{(Rotational Equilibrium)}$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts at free surface of water and on outside of dam

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

Into the vertical force equation: $F_v = \int p dA_y = \int_{x_A}^{x_B} \rho \cdot g \cdot h \cdot b \, dx = \rho \cdot g \cdot b \cdot \int_{x_A}^{x_B} (H - y) \, dx$

From the definition of the dam contour: $x \cdot y - A \cdot y = B$ Therefore: $y = \frac{B}{x - A}$ and $x_A = \frac{10 \cdot \text{ft}^2}{9 \cdot \text{ft}} + 1 \cdot \text{ft} \quad x_A = 2.11 \cdot \text{ft}$

Into the force equation:
$$F_v = \rho \cdot g \cdot b \cdot \int_{x_A}^{x_B} \left(H - \frac{B}{x - A} \right) dx = \rho \cdot g \cdot b \cdot \left[H \cdot (x_B - x_A) - B \cdot \ln \left(\frac{x_B - A}{x_A - A} \right) \right]$$
 Substituting known values:

$$F_v = 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 160 \cdot \text{ft} \times \left[9 \cdot \text{ft} \times (7.0 \cdot \text{ft} - 2.11 \cdot \text{ft}) - 10 \cdot \text{ft}^2 \times \ln \left(\frac{7.0 - 1}{2.11 - 1} \right) \right] \cdot \frac{\text{lb} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}}$$

$$F_v = 2.71 \times 10^5 \cdot \text{lb} \cdot \text{ft}$$

To find the line of action of the force: $x' \cdot F_v = \int x \, dF_v$ where $dF_v = \rho \cdot g \cdot b \cdot \left(H - \frac{B}{x - A} \right) \cdot dx$ Therefore:

$$x' = \frac{x' \cdot F_v}{F_v} = \frac{1}{F_v} \cdot \int_{x_A}^{x_B} x \cdot \rho \cdot g \cdot b \cdot \left(H - \frac{B}{x - A} \right) dx = \frac{1}{H \cdot (x_B - x_A) - B \cdot \ln \left(\frac{x_B - A}{x_A - A} \right)} \cdot \int_{x_A}^{x_B} \left(H \cdot x - \frac{B \cdot x}{x - A} \right) dx$$

Evaluating the integral:
$$x' = \frac{\frac{H}{2} \cdot (x_B^2 - x_A^2) - B \cdot (x_B - x_A) - B \cdot A \cdot \ln \left(\frac{x_B - A}{x_A - A} \right)}{H \cdot (x_B - x_A) - B \cdot \ln \left(\frac{x_B - A}{x_A - A} \right)}$$
 Substituting known values we get:

$$x' = \frac{\frac{9 \cdot \text{ft}}{2} \times (7^2 - 2.11^2) \cdot \text{ft}^2 - 10 \cdot \text{ft}^2 \times (7 - 2.11) \cdot \text{ft} - 10 \cdot \text{ft}^2 \times 1 \cdot \text{ft} \times \ln \left(\frac{7 - 1}{2.11 - 1} \right)}{9 \cdot \text{ft} \times (7 - 2.11) \cdot \text{ft} - 10 \cdot \text{ft}^2 \times \ln \left(\frac{7 - 1}{2.11 - 1} \right)}$$

$$x' = 4.96 \cdot \text{ft}$$

To determine whether or not the water can overturn the dam, we need the horizontal force and its line of action:

$$F_H = p_c \cdot A = \rho \cdot g \cdot \frac{H}{2} \cdot H \cdot b = \frac{\rho \cdot g \cdot b \cdot H^2}{2}$$

Substituting values:
$$F_H = \frac{1}{2} \times 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times 160 \cdot \text{ft} \times (9 \cdot \text{ft})^2 \times \frac{\text{lb} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}}$$

$$F_H = 4.05 \times 10^5 \cdot \text{lb} \cdot \text{ft}$$

For the line of action:
$$h' = h_c + \frac{I_{xx}}{h_c \cdot A} \quad \text{where} \quad h_c = \frac{H}{2} \quad A = H \cdot b \quad I_{xx} = \frac{b \cdot H^3}{12}$$

Therefore:
$$h' = \frac{H}{2} + \frac{b \cdot H^3}{12} \cdot \frac{2}{H} \cdot \frac{1}{b \cdot H} = \frac{H}{2} + \frac{H}{6} = \frac{2}{3} \cdot H \quad h' = \frac{2}{3} \cdot 9 \cdot \text{ft} \quad h' = 6.00 \cdot \text{ft}$$

Taking moments of the hydrostatic forces about the origin:

$$M_w = F_H \cdot (H - h') - F_v \cdot x' \quad M_w = 4.05 \times 10^5 \cdot \text{lb} \cdot \text{ft} \times (9 - 6) \cdot \text{ft} - 2.71 \times 10^5 \cdot \text{lb} \cdot \text{ft} \times 4.96 \cdot \text{ft} \quad M_w = -1.292 \times 10^5 \cdot \text{lb} \cdot \text{ft}$$

The negative sign indicates that this is a clockwise moment about the origin. Since the weight of the dam will also contribute a clockwise moment about the origin, these two moments should not cause the dam to tip to the left.

Therefore, the water can not overturn the dam.

Problem 3.61

(Difficulty: 2)

3.61 The quarter cylinder AB is 10 ft long. Calculate magnitude, direction, and location of the resultant force of the water on AB .

Given: All the parameters are shown in the figure.

Assumptions: Fluid is incompressible and static

Find: The resultant force.

Solution: Apply the hydrostatic relations for pressure as a function of depth and for the location of forces on submerged objects.

$$\Delta p = \rho g h$$

A freebody diagram for the cylinder is:

The force balance in the horizontal direction yields that horizontal force is due to the water pressure:

$$F_H = P_H$$

Where the depth is the distance to the centroid of the horizontal area $(8 + 5/2 \text{ ft})$:

$$F_H = \gamma h_c A = 62.4 \frac{\text{lb}}{\text{ft}^3} \times \left(8 \text{ ft} + \frac{5 \text{ ft}}{2}\right) \times (5 \text{ ft} \times 10 \text{ ft}) = 32800 \text{ lb}$$

$$P_H = 32800 \text{ lbf}$$

The force in the vertical direction can be calculated as the weight of a volume of water that is 8 ft + 5 ft = 13 ft deep less the weight of water that would be in the quarter cylinder. This force is then:

$$P_V = F_V - W = 62.4 \frac{\text{lbf}}{\text{ft}^3} \times 13 \text{ ft} \times (5 \text{ ft} \times 10 \text{ ft}) - 62.4 \frac{\text{lbf}}{\text{ft}^3} \times \frac{\pi}{4} \times (5 \text{ ft})^2 \times (10 \text{ ft}) = 28308 \text{ lbf}$$

The total resultant force is the vector sum of the two forces:

$$P = \sqrt{P_H^2 + P_V^2} = \sqrt{(32800 \text{ lbf})^2 + (28308 \text{ lbf})^2} = 43300 \text{ lbf}$$

The angle with respect to the horizontal is:

$$\theta = \tan^{-1} \left(\frac{P_V}{P_H} \right) = \tan^{-1} \left(\frac{28308 \text{ lbf}}{32800 \text{ lbf}} \right) = 40.9^\circ$$

So the force acts on the quarter cylinder surface point at an angle of $\theta = 40.9^\circ$ with respect to the horizontal.

Problem 3.62

(Difficulty: 2)

3.62 Calculate the magnitude, direction (horizontal and vertical components are acceptable), and line of action of the resultant force exerted by the water on the cylindrical gate 30 ft long.

Assumptions: Fluid is incompressible and static

Find: The resultant forces.

Solution: Apply the hydrostatic relations for pressure as a function of depth and for the location of forces on submerged objects.

$$\Delta p = \rho g h$$

A free body diagram of the gate is

The horizontal force is calculated as:

$$P_H = F_H$$

Where the depth is the distance to the centroid of the horizontal area (5 ft):

$$F_H = \gamma h_c A = 62.4 \frac{\text{lb}}{\text{ft}^3} \times 5 \text{ ft} \times (10 \text{ ft} \times 30 \text{ ft}) = 93600 \text{ lb}$$

$$P_H = 93600 \text{ lb}$$

The force in the vertical direction can be calculated as the weight of a volume of water that is 10 ft deep less the weight of water that would be in the quarter cylinder. This force is then:

$$P_V = F_V - W = \gamma h_c A - \gamma \nabla$$

$$P_V = 62.4 \frac{lb f}{ft^3} \times 10 ft \times (10 ft \times 30 ft) - 62.4 \frac{lb f}{ft^3} \times \left[10 ft \times (10 ft \times 30 ft) - \frac{\pi}{4} \times (10 ft)^2 \times 30 ft \right] = 147000 lb f$$

The total resultant force is the vector sum of the two forces:

$$P = \sqrt{P_H^2 + P_V^2} = \sqrt{(93600 lb f)^2 + (147000 lb f)^2} = 174200 lb f$$

The direction can be calculated as:

$$\theta = \tan^{-1} \left(\frac{P_V}{P_H} \right) = \tan^{-1} \left(\frac{147000 lb f}{93600 lb f} \right) = 57.5^\circ$$

Problem 3.63

(Difficulty: 2)

3.63 A hemispherical shell 1.2 m in diameter is connected to the vertical wall of a tank containing water. If the center of the shell is 1.8 m below the water surface, what are the vertical and horizontal force components on the shell? On the top half of the shell?

Assumptions: Fluid is incompressible and static

Find: The resultant forces.

Solution: Apply the hydrostatic relations for pressure as a function of depth and for the location of forces on submerged objects.

$$\Delta p = \rho g h$$

A free body diagram of the system is

The force in the horizontal direction can be calculated using the distance to the centroid (1.8 m) as:

$$F_H = \gamma h_c A = 9.81 \frac{\text{kN}}{\text{m}^3} \times 1.8 \text{ m} \times \left(\frac{1}{4} \times \pi \times (1.2 \text{ m})^2 \right) = 19.97 \text{ kN}$$

The force in the vertical direction is the buoyancy force due to the volume displaced by the shell:

$$F_V = \gamma V = 9.81 \frac{\text{kN}}{\text{m}^3} \times \frac{1}{2} \times \frac{1}{6} \times \pi \times (1.2 \text{ m})^3 = 4.44 \text{ kN}$$

For the top shell, the horizontal force acts at:

$$y_c = 1.8 \text{ m} - \frac{4 \times 0.6 \text{ m}}{3\pi} = 1.545 \text{ m}$$

The horizontal force on the top half of the shell is then:

$$F_H = \gamma y_c A = 9.81 \frac{kN}{m^3} \times 1.545 m \times \frac{\pi}{8} \times (1.2 m)^2 = 8.57 kN$$

The vertical force on the top half of the shell is the buoyancy force:

$$F_V = pA = 9.81 \frac{kN}{m^3} \times 1.8 m \times \frac{\pi}{8} \times (1.2 m)^2 - 9.81 \frac{kN}{m^3} \times \frac{1}{4} \times \frac{1}{6} \times \pi \times (1.2 m)^3 = 7.77 kN$$

Problem 3.64

[Difficulty: 4]

3.64 A gate, in the shape of a quarter-cylinder, hinged at *A* and sealed at *B*, is 3 m wide. The bottom of the gate is 4.5 m below the water surface. Determine the force on the stop at *B* if the gate is made of concrete; $R = 3$ m.

Given: Gate geometry

Find: Force on stop *B*

Solution:

Basic equations

$$\frac{dp}{dh} = \rho \cdot g$$

$$\Sigma M_A = 0$$

Weights for computing F_V

Assumptions: static fluid; $\rho = \text{constant}$; p_{atm} on other side

For incompressible fluid $p = \rho \cdot g \cdot h$ where p is gage pressure and h is measured downwards

We need to compute force (including location) due to water on curved surface and underneath. For curved surface we could integrate pressure, but here we use the concepts that F_V (see sketch) is equivalent to the weight of fluid above, and F_H is equivalent to the force on a vertical flat plate. Note that the sketch only shows forces that will be used to compute the moment at *A*

For F_V

$$F_V = W_1 - W_2$$

with

$$W_1 = \rho \cdot g \cdot w \cdot D \cdot R = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3 \cdot \text{m} \times 4.5 \cdot \text{m} \times 3 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad W_1 = 397 \cdot \text{kN}$$

$$W_2 = \rho \cdot g \cdot w \cdot \frac{\pi \cdot R^2}{4} = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3 \cdot \text{m} \times \frac{\pi}{4} \times (3 \cdot \text{m})^2 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad W_2 = 208 \cdot \text{kN}$$

$$F_V = W_1 - W_2 \quad F_V = 189 \cdot \text{kN}$$

with x given by

$$F_V \cdot x = W_1 \cdot \frac{R}{2} - W_2 \cdot \frac{4 \cdot R}{3 \cdot \pi} \quad \text{or} \quad x = \frac{W_1}{F_V} \cdot \frac{R}{2} - \frac{W_2}{F_V} \cdot \frac{4 \cdot R}{3 \cdot \pi}$$

$$x = \frac{397}{189} \times \frac{3 \cdot \text{m}}{2} - \frac{208}{189} \times \frac{4}{3 \cdot \pi} \times 3 \cdot \text{m} \quad x = 1.75 \text{ m}$$

For F_H

Computing equations

$$F_H = p_c \cdot A \quad y' = y_c + \frac{I_{xx}}{A \cdot y_c}$$

Hence
$$F_H = p_c \cdot A = \rho \cdot g \cdot \left(D - \frac{R}{2}\right) \cdot w \cdot R$$

$$F_H = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times \left(4.5 \cdot \text{m} - \frac{3 \cdot \text{m}}{2}\right) \times 3 \cdot \text{m} \times 3 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad F_H = 265 \cdot \text{kN}$$

The location of this force is

$$y' = y_c + \frac{I_{xx}}{A \cdot y_c} = \left(D - \frac{R}{2}\right) + \frac{w \cdot R^3}{12} \times \frac{1}{w \cdot R \cdot \left(D - \frac{R}{2}\right)} = D - \frac{R}{2} + \frac{R^2}{12 \cdot \left(D - \frac{R}{2}\right)}$$

$$y' = 4.5 \cdot \text{m} - \frac{3 \cdot \text{m}}{2} + \frac{(3 \cdot \text{m})^2}{12 \times \left(4.5 \cdot \text{m} - \frac{3 \cdot \text{m}}{2}\right)} \quad y' = 3.25 \text{ m}$$

The force F_1 on the bottom of the gate is $F_1 = p \cdot A = \rho \cdot g \cdot D \cdot w \cdot R$

$$F_1 = 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 4.5 \cdot \text{m} \times 3 \cdot \text{m} \times 3 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad F_1 = 397 \cdot \text{kN}$$

For the concrete gate (SG = 2.4 from Table A.2)

$$W_{\text{Gate}} = \text{SG} \cdot \rho \cdot g \cdot w \cdot \frac{\pi \cdot R^2}{4} = 2.4 \cdot 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3 \cdot \text{m} \times \frac{\pi}{4} \times (3 \cdot \text{m})^2 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad W_{\text{Gate}} = 499 \cdot \text{kN}$$

Hence, taking moments about A
$$F_B \cdot R + F_1 \cdot \frac{R}{2} - W_{\text{Gate}} \cdot \frac{4 \cdot R}{3 \cdot \pi} - F_V \cdot x - F_H \cdot [y' - (D - R)] = 0$$

$$F_B = \frac{4}{3 \cdot \pi} \cdot W_{\text{Gate}} + \frac{x}{R} \cdot F_V + \frac{[y' - (D - R)]}{R} \cdot F_H - \frac{1}{2} \cdot F_1$$

$$F_B = \frac{4}{3 \cdot \pi} \times 499 \cdot \text{kN} + \frac{1.75}{3} \times 189 \cdot \text{kN} + \frac{[3.25 - (4.5 - 3)]}{3} \times 265 \cdot \text{kN} - \frac{1}{2} \times 397 \cdot \text{kN}$$

$$F_B = 278 \cdot \text{kN}$$

Problem 3.65

[Difficulty: 3]

3.65 A cylindrical weir has a diameter of 3 m and a length of 6 m. Find the magnitude and direction of the resultant force acting on the weir from the water.

Given: Cylindrical weir as shown; liquid is water

Find: Magnitude and direction of the resultant force of the water on the weir

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g$$

(Hydrostatic Pressure - h is positive downwards from free surface)

$$\vec{dF_R} = -p \cdot d\vec{A}$$

(Hydrostatic Force)

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts on free surfaces and on the first quadrant of the cylinder

Using the coordinate system shown in the diagram at the right:

$$F_{Rx} = \vec{F_R} \cdot \vec{i} = - \int p d\vec{A} \cdot \vec{i} = - \int p \cdot \cos(\theta + 90^\circ) dA = \int p \cdot \sin(\theta) dA$$

$$F_{Ry} = \vec{F_R} \cdot \vec{j} = - \int p d\vec{A} \cdot \vec{j} = - \int p \cdot \cos(\theta) dA \quad \text{Now since } dA = L \cdot R \cdot d\theta \text{ it follows that}$$

$$F_{Rx} = \int_0^{\frac{3\pi}{2}} p \cdot L \cdot R \cdot \sin(\theta) d\theta \quad \text{and} \quad F_{Ry} = - \int_0^{\frac{3\pi}{2}} p \cdot L \cdot R \cdot \cos(\theta) d\theta$$

Next, we integrate the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$ Now over the range $0 \leq \theta \leq \pi$ $h_1 = R(1 - \cos(\theta))$

Over the range $\pi \leq \theta \leq \frac{3\pi}{2}$ $h_2 = -R \cdot \cos(\theta)$

Therefore we can express the pressure in terms of θ and substitute into the force equations:

$$F_{Rx} = \int_0^{\frac{3\pi}{2}} p \cdot L \cdot R \cdot \sin(\theta) d\theta = \int_0^{\pi} \rho \cdot g \cdot R \cdot (1 - \cos(\theta)) \cdot L \cdot R \cdot \sin(\theta) d\theta - \int_{\pi}^{\frac{3\pi}{2}} \rho \cdot g \cdot R \cdot \cos(\theta) \cdot L \cdot R \cdot \sin(\theta) d\theta$$

$$F_{Rx} = \rho \cdot g \cdot R^2 \cdot L \cdot \int_0^{\pi} (1 - \cos(\theta)) \cdot \sin(\theta) d\theta - \rho \cdot g \cdot R^2 \cdot L \cdot \int_{\pi}^{\frac{3\pi}{2}} \cos(\theta) \cdot \sin(\theta) d\theta$$

$$F_{Rx} = \rho \cdot g \cdot R^2 \cdot L \cdot \left[\int_0^{\pi} (1 - \cos(\theta)) \cdot \sin(\theta) d\theta - \int_{\pi}^{\frac{3 \cdot \pi}{2}} \cos(\theta) \cdot \sin(\theta) d\theta \right] = \rho \cdot g \cdot R^2 \cdot L \cdot \left(2 - \frac{1}{2} \right) = \frac{3}{2} \cdot \rho \cdot g \cdot R^2 \cdot L$$

Substituting known values: $F_{Rx} = \frac{3}{2} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (1.5 \cdot \text{m})^2 \times 6 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $F_{Rx} = 198.5 \cdot \text{kN}$

Similarly we can calculate the vertical force component:

$$F_{Ry} = - \int_0^{\frac{3 \cdot \pi}{2}} p \cdot L \cdot R \cdot \cos(\theta) d\theta = - \left[\int_0^{\pi} \rho \cdot g \cdot R \cdot (1 - \cos(\theta)) \cdot L \cdot R \cdot \cos(\theta) d\theta - \int_{\pi}^{\frac{3 \cdot \pi}{2}} \rho \cdot g \cdot R \cdot \cos(\theta) \cdot L \cdot R \cdot \cos(\theta) d\theta \right]$$

$$F_{Ry} = - \rho \cdot g \cdot R^2 \cdot L \cdot \left[\int_0^{\pi} (1 - \cos(\theta)) \cdot \cos(\theta) d\theta - \int_{\pi}^{\frac{3 \cdot \pi}{2}} (\cos(\theta))^2 d\theta \right] = \rho \cdot g \cdot R^2 \cdot L \cdot \left(\frac{\pi}{2} + \frac{3 \cdot \pi}{4} - \frac{\pi}{2} \right) = \frac{3 \cdot \pi}{4} \cdot \rho \cdot g \cdot R^2 \cdot L$$

Substituting known values: $F_{Ry} = \frac{3 \cdot \pi}{4} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (1.5 \cdot \text{m})^2 \times 6 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $F_{Ry} = 312 \cdot \text{kN}$

Now since the weir surface in contact with the water is a circular arc, all elements dF of the force, and hence the line of action of the resultant force, must pass through the pivot. Thus:

Magnitude of the resultant force: $F_R = \sqrt{(198.5 \cdot \text{kN})^2 + (312 \cdot \text{kN})^2}$ $F_R = 370 \cdot \text{kN}$

The line of action of the force: $\alpha = \text{atan}\left(\frac{312 \cdot \text{kN}}{198.5 \cdot \text{kN}}\right)$ $\alpha = 57.5 \cdot \text{deg}$

Problem 3.66

[Difficulty: 3]

3.66 A curved surface is formed as a quarter of a circular cylinder with $R = 0.750$ m as shown. The surface is $w = 3.55$ m wide. Water stands to the right of the curved surface to depth $H = 0.650$ m. Calculate the vertical hydrostatic force on the curved surface. Evaluate the line of action of this force. Find the magnitude and line of action of the horizontal force on the surface.

Given: Curved surface, in shape of quarter cylinder, with given radius R and width w ; water stands to depth H .
 $R = 0.750\text{ m}$ $w = 3.55\text{ m}$ $H = 0.650\text{ m}$

Find: Magnitude and line of action of (a) vertical force and (b) horizontal force on the curved surface

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad \text{(Hydrostatic Pressure - } h \text{ is positive downwards from free surface)}$$

$$F_v = \int p \, dA_y \quad \text{(Vertical Hydrostatic Force)}$$

$$F_H = p_c \cdot A \quad \text{(Horizontal Hydrostatic Force)}$$

$$x' \cdot F_v = \int x \, dF_v \quad \text{(Moment of vertical force)}$$

$$h' = h_c + \frac{I_{xx}}{h_c \cdot A} \quad \text{(Line of action of horizontal force)}$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts on free surface of the water and on the left side of the curved surface

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

From the geometry: $h = H - R \cdot \sin(\theta)$ $y = R \cdot \sin(\theta)$ $x = R \cdot \cos(\theta)$ $dA = w \cdot R \cdot d\theta$

$$\theta_1 = \text{asin}\left(\frac{H}{R}\right) \quad \theta_1 = \text{asin}\left(\frac{0.650}{0.750}\right) \quad \theta_1 = 1.048\text{ rad}$$

Therefore the vertical component of the hydrostatic force is:

$$F_v = \int p \, dA_y = \int \rho \cdot g \cdot h \cdot \sin(\theta) \, dA = \int_0^{\theta_1} \rho \cdot g \cdot (H - R \cdot \sin(\theta)) \cdot \sin(\theta) \cdot w \cdot R \, d\theta$$

$$F_v = \rho \cdot g \cdot w \cdot R \cdot \int_0^{\theta_1} [H \cdot \sin(\theta) - R \cdot (\sin(\theta))^2] \, d\theta = \rho \cdot g \cdot w \cdot R \cdot \left[H \cdot (1 - \cos(\theta_1)) - R \cdot \left(\frac{\theta_1}{2} - \frac{\sin(2\theta_1)}{4} \right) \right]$$

$$F_v = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3.55 \cdot \text{m} \times 0.750 \cdot \text{m} \times \left[0.650 \cdot \text{m} \times (1 - \cos(1.048 \cdot \text{rad})) - 0.750 \cdot \text{m} \times \left(\frac{1.048}{2} - \frac{\sin(2 \times 1.048 \cdot \text{rad})}{4} \right) \right] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

$$F_v = 2.47 \cdot \text{kN}$$

To calculate the line of action of this force:

$$x' \cdot F_v = \int R \cdot \cos(\theta) \cdot \rho \cdot g \cdot h \cdot \sin(\theta) dA = \rho \cdot g \cdot w \cdot R^2 \cdot \int_0^{\theta_1} [H \cdot \sin(\theta) \cdot \cos(\theta) - R \cdot (\sin(\theta))^2 \cdot \cos(\theta)] d\theta$$

$$\text{Evaluating the integral: } x' \cdot F_v = \rho \cdot g \cdot w \cdot R^2 \cdot \left[\frac{H}{2} \cdot (\sin(\theta_1))^2 - \frac{R}{3} \cdot (\sin(\theta_1))^3 \right] \quad \text{Therefore we may find the line of action:}$$

$$x' = \frac{x' \cdot F_v}{F_v} = \frac{\rho \cdot g \cdot w \cdot R^2}{F_v} \cdot \left[\frac{H}{2} \cdot (\sin(\theta_1))^2 - \frac{R}{3} \cdot (\sin(\theta_1))^3 \right] \quad \text{Substituting in known values: } \sin(\theta_1) = \frac{0.650}{0.750}$$

$$x' = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3.55 \cdot \text{m} \times (0.750 \cdot \text{m})^2 \times \frac{1}{2.47 \times 10^3} \cdot \frac{1}{\text{N}} \times \left[\frac{0.650 \cdot \text{m}}{2} \times \left(\frac{0.650}{0.750} \right)^2 - \frac{0.750 \cdot \text{m}}{3} \times \left(\frac{0.650}{0.750} \right)^3 \right] \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

$$x' = 0.645 \text{ m}$$

$$\text{For the horizontal force: } F_H = p_c \cdot A = \rho \cdot g \cdot h_c \cdot H \cdot w = \rho \cdot g \cdot \frac{H}{2} \cdot H \cdot w = \frac{\rho \cdot g \cdot H^2 \cdot w}{2}$$

$$F_H = \frac{1}{2} \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times (0.650 \cdot \text{m})^2 \times 3.55 \cdot \text{m} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$$

$$F_H = 7.35 \cdot \text{kN}$$

$$\text{For the line of action of the horizontal force: } h' = h_c + \frac{I_{xx}}{h_c \cdot A} \quad \text{where} \quad I_{xx} = \frac{w \cdot H^3}{12} \quad A = w \cdot H \quad \text{Therefore:}$$

$$h' = h_c + \frac{I_{xx}}{h_c \cdot A} = \frac{H}{2} + \frac{w \cdot H^3}{12} \cdot \frac{2}{H} \cdot \frac{1}{w \cdot H} = \frac{H}{2} + \frac{H}{6} = \frac{2}{3} \cdot H \quad h' = \frac{2}{3} \times 0.650 \cdot \text{m}$$

$$h' = 0.433 \text{ m}$$

Problem 3.67

[Difficulty: 2]

3.67 If you throw an anchor out of your canoe but the rope is too short for the anchor to rest on the bottom of the pond, will your canoe float higher, lower, or stay the same? Prove your answer.

Given: Canoe floating in a pond

Find: What happens when an anchor with too short of a line is thrown from canoe

Solution:

Governing equation:

$$F_B = \rho_w g V_{disp} = W$$

Before the anchor is thrown from the canoe the buoyant force on the canoe balances out the weight of the canoe and anchor:

$$F_{B_1} = W_{canoe} + W_{anchor} = \rho_w g V_{canoe_1}$$

The anchor weight can be expressed as

$$W_{anchor} = \rho_a g V_a$$

so the initial volume displaced by the canoe can be written as

$$V_{canoe_1} = \frac{W_{canoe}}{\rho_w g} + \frac{\rho_a}{\rho_w} V_a$$

After throwing the anchor out of the canoe there will be buoyant forces acting on the canoe and the anchor. Combined, these buoyant forces balance the canoe weight and anchor weight:

$$F_{B_2} = W_{canoe} + W_{anchor} = \rho_w g V_{canoe_2} + \rho_w g V_a$$

$$V_{canoe_2} = \frac{W_{canoe}}{\rho_w g} + \frac{W_a}{\rho_w g} - V_a$$

Using the anchor weight,

$$V_{canoe_2} = \frac{W_{canoe}}{\rho_w g} + \frac{\rho_a}{\rho_w} V_a - V_a$$

Hence the volume displaced by the canoe after throwing the anchor in is less than when the anchor was in the canoe, meaning that the canoe is floating higher.

Problem 3.68

[Difficulty: 4]

3.68 The cylinder shown is supported by an incompressible liquid of density ρ , and is hinged along its length. The cylinder, of mass M , length L , and radius R , is immersed in liquid to depth H . Obtain a general expression for the cylinder specific gravity versus the ratio of liquid depth to cylinder radius, $\alpha = H/R$, needed to hold the cylinder in equilibrium for $0 \leq \alpha < 1$. Plot the results.

Given: Cylinder of mass M , length L , and radius R is hinged along its length and immersed in an incompressible liquid to depth H .

Find: General expression for the cylinder specific gravity as a function of $\alpha = H/R$ needed to hold the cylinder in equilibrium for α ranging from 0 to 1.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$\frac{dp}{dh} = \rho \cdot g \quad (\text{Hydrostatic Pressure - } h \text{ is positive downwards from free surface})$$

$$F_v = \int p \, dA_y \quad (\text{Vertical Hydrostatic Force})$$

$$\Sigma M = 0 \quad (\text{Rotational Equilibrium})$$

Assumptions:

- (1) Static fluid
- (2) Incompressible fluid
- (3) Atmospheric pressure acts on free surface of the liquid.

The moments caused by the hydrostatic force and the weight of the cylinder about the hinge need to balance each other.

Integrating the hydrostatic pressure equation: $p = \rho \cdot g \cdot h$

$$dF_v = dF \cdot \cos(\theta) = p \cdot dA \cdot \cos(\theta) = \rho \cdot g \cdot h \cdot w \cdot R \cdot d\theta \cdot \cos(\theta)$$

Now the depth to which the cylinder is submerged is $H = h + R \cdot (1 - \cos(\theta))$

Therefore $h = H - R \cdot (1 - \cos(\theta))$ and into the vertical force equation:

$$dF_v = \rho \cdot g \cdot [H - R \cdot (1 - \cos(\theta))] \cdot w \cdot R \cdot \cos(\theta) \cdot d\theta = \rho \cdot g \cdot w \cdot R^2 \cdot \left[\frac{H}{R} - (1 - \cos(\theta)) \right] \cdot \cos(\theta) \cdot d\theta$$

$$dF_v = \rho \cdot g \cdot w \cdot R^2 \cdot [(\alpha - 1) \cdot \cos(\theta) + (\cos(\theta))^2] \cdot d\theta = \rho \cdot g \cdot w \cdot R^2 \cdot \left[(\alpha - 1) \cdot \cos(\theta) + \frac{1 + \cos(2\theta)}{2} \right] \cdot d\theta$$

Now as long as α is not greater than 1, the net horizontal hydrostatic force will be zero due to symmetry, and the vertical force is:

$$F_v = \int_{-\theta_{\max}}^{\theta_{\max}} 1 \, dF_v = \int_0^{\theta_{\max}} 2 \, dF_v \quad \text{where} \quad \cos(\theta_{\max}) = \frac{R - H}{R} = 1 - \alpha \quad \text{or} \quad \theta_{\max} = \arccos(1 - \alpha)$$

$$F_v = 2\rho \cdot g \cdot w \cdot R^2 \cdot \int_0^{\theta_{\max}} \left[(\alpha - 1) \cdot \cos(\theta) + \frac{1}{2} + \frac{1}{2} \cdot \cos(2\theta) \right] d\theta \quad \text{Now upon integration of this expression we have:}$$

$$F_v = \rho \cdot g \cdot w \cdot R^2 \cdot [\alpha \cos(1 - \alpha) - (1 - \alpha) \cdot \sqrt{\alpha \cdot (2 - \alpha)}]$$

The line of action of the vertical force due to the liquid is through the centroid of the displaced liquid, i.e., through the center of the cylinder

The weight of the cylinder is given by: $W = M \cdot g = \rho_c \cdot V \cdot g = SG \cdot \rho \cdot \pi \cdot R^2 \cdot w \cdot g$ where ρ is the density of the fluid and $SG = \frac{\rho_c}{\rho}$

The line of action of the weight is also through the center of the cylinder. Taking moment about the hinge we get:

$$\Sigma M_O = W \cdot R - F_v \cdot R = 0 \quad \text{or in other words} \quad W = F_v \quad \text{and therefore:}$$

$$SG \cdot \rho \cdot \pi \cdot R^2 \cdot w \cdot g = \rho \cdot g \cdot w \cdot R^2 \cdot [\alpha \cos(1 - \alpha) - (1 - \alpha) \cdot \sqrt{\alpha \cdot (2 - \alpha)}] \quad SG = \frac{1}{\pi} \cdot [\alpha \cos(1 - \alpha) - (1 - \alpha) \cdot \sqrt{\alpha \cdot (2 - \alpha)}]$$

Problem 3.69

[Difficulty: 2]

3.69 A hydrometer is a specific gravity indicator, the value being indicated by the level at which the free surface intersects the stem when floating in a liquid. The 1.0 mark is the level when in distilled water. For the unit shown, the immersed volume in distilled water is 15 cm^3 . The stem is 6 mm in diameter. Find the distance, h , from the 1.0 mark to the surface when the hydrometer is placed in a nitric acid solution of specific gravity 1.5.

Given: Hydrometer as shown, submerged in nitric acid. When submerged in water, $h = 0$ and the immersed volume is 15 cubic cm.
 $SG = 1.5$ $d = 6 \text{ mm}$

Find: The distance h when immersed in nitric acid.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $F_{\text{buoy}} = \rho \cdot g \cdot V_d$ (Buoyant force is equal to weight of displaced fluid)

Assumptions: (1) Static fluid
 (2) Incompressible fluid

Taking a free body diagram of the hydrometer: $\Sigma F_z = 0 \quad -M \cdot g + F_{\text{buoy}} = 0$

Solving for the mass of the hydrometer: $M = \frac{F_{\text{buoy}}}{g} = \rho \cdot V_d$

When immersed in water: $M = \rho_w \cdot V_w$ When immersed in nitric acid: $M = \rho_n \cdot V_n$

Since the mass of the hydrometer is the same in both cases: $\rho_w \cdot V_w = \rho_n \cdot V_n$

When the hydrometer is in the nitric acid: $V_n = V_w - \frac{\pi}{4} \cdot d^2 \cdot h$ $\rho_n = SG \cdot \rho_w$

Therefore: $\rho_w \cdot V_w = SG \cdot \rho_w \cdot \left(V_w - \frac{\pi}{4} \cdot d^2 \cdot h \right)$ Solving for the height h :

$$V_w = SG \cdot \left(V_w - \frac{\pi}{4} \cdot d^2 \cdot h \right) \quad V_w \cdot (1 - SG) = -SG \cdot \frac{\pi}{4} \cdot d^2 \cdot h$$

$$h = V_w \cdot \left(\frac{SG - 1}{SG} \right) \cdot \frac{4}{\pi \cdot d^2} \quad h = 15 \cdot \text{cm}^3 \times \left(\frac{1.5 - 1}{1.5} \right) \times \frac{4}{\pi \times (6 \cdot \text{mm})^2} \times \left(\frac{10 \cdot \text{mm}}{\text{cm}} \right)^3 \quad h = 177 \cdot \text{mm}$$

Problem 3.70

(Difficulty: 2)

3.70 A cylindrical can 76 mm in diameter and 152 mm high, weighing 1.11 N, contains water to a depth of 76 mm. When this can is placed in water, how deep will it sink?

Find: The depth it will sink.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

A free body diagram on the can is

We have the force balance equation in the vertical direction as:

$$F_b - W_{can} - W_{canwater} = 0$$

The buoyancy force can be calculated as:

$$F_b = \gamma_{water} V_{can} = 9810 \frac{N}{m^3} \times \frac{\pi}{4} \times (0.076 m)^2 \times x m = 44.50 X x N$$

We also have:

$$W_{can} = 1.11 N$$

$$W_{canwater} = \gamma_{water} V_{canwater} = 9810 \frac{N}{m^3} \times \frac{\pi}{4} \times (0.076 m)^3 = 3.38 N$$

Thus making a force balance for which the net force is zero at equilibrium

$$44.50x = 1.11 \text{ N} + 3.38 \text{ N} = 4.49 \text{ N}$$

$$x = 0.1009 \text{ m} = 100.9 \text{ mm}$$

So this can will sink to depth of 100.9 mm.

Problem 3.71

(Difficulty: 1)

3.71 If the 10 ft long box is floating on the oil water system, calculate how much the box and its contents must weigh.

Find: The weight of the box and its contents.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

The force balance equation in the vertical direction:

$$F_B - W_B = 0$$

$$F_B = \gamma_{oil} V + \gamma_{water} V$$

Thus

$$F_B = 0.8 \times 62.4 \frac{\text{lb}_f}{\text{ft}^3} \times 2 \text{ ft} \times 8 \text{ ft} \times 10 \text{ ft} + 62.4 \frac{\text{lb}_f}{\text{ft}^3} \times 1 \text{ ft} \times 8 \text{ ft} \times 10 \text{ ft} = 12980 \text{ lb}_f$$

So the box and its contents must weigh:

$$W_B = 12980 \text{ lb}_f$$

Problem 3.72

(Difficulty: 2)

3.72 The timber weighs $40 \frac{\text{lb}}{\text{ft}^3}$ and is held in a horizontal position by the concrete $\left(150 \frac{\text{lb}}{\text{ft}^3}\right)$ anchor. Calculate the minimum total weight which the anchor may have.

Find: The minimum total weight the anchor may have.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

For the buoyancy force we have:

$$F_{bt} = \gamma_{\text{water}} V_t$$

$$F_{bt} = 62.4 \frac{\text{lb}}{\text{ft}^3} \times \left(\frac{6}{12} \text{ ft}\right) \times \left(\frac{6}{12} \text{ ft}\right) \times (20 \text{ ft}) = 312 \text{ lbf}$$

The weight of the timber is:

$$W_t = \gamma_t V_t$$

$$W_t = 40 \frac{\text{lb}}{\text{ft}^3} \times \left(\frac{6}{12} \text{ ft}\right) \times \left(\frac{6}{12} \text{ ft}\right) \times (20 \text{ ft}) = 200 \text{ lbf}$$

At the horizontal position we take moments about the pivot:

$$F_a L + W_t \frac{L}{2} - F_{bt} \frac{L}{2} = 0$$

$$F_a = \frac{1}{2} F_{bt} - \frac{1}{2} W_t = \frac{1}{2} \times (312 \text{ lbf} - 200 \text{ lbf}) = 56 \text{ lbf}$$

$$F_a = F_{ba} - W_a$$

The weight of the anchor is:

$$W_a = \gamma_a V_a$$

The buoyancy force on the anchor is:

$$F_{ba} = \gamma_{water} V_a$$

$$\gamma_a V_a - \gamma_{water} V_a = 56 \text{ lbf}$$

$$V_a = \frac{56 \text{ lbf}}{\left(150 \frac{\text{lbf}}{\text{ft}^3} - 62.4 \frac{\text{lbf}}{\text{ft}^3}\right)} = 0.64 \text{ ft}^3$$

So the weight is:

$$W_a = \gamma_a V_a = 150 \frac{\text{lbf}}{\text{ft}^3} \times 0.64 \text{ ft}^3 = 96 \text{ lbf}$$

Problem 3.73

[Difficulty: 3]

3.73 Find the specific weight of the sphere shown if its volume is 0.025m^3 . State all assumptions. What is the equilibrium position of the sphere if the weight is removed?

Given: Data on sphere and weight

Find: SG of sphere; equilibrium position when freely floating

Solution:

Basic equation $F_B = \rho \cdot g \cdot V$ and $\Sigma F_z = 0$ $\Sigma F_z = 0 = T + F_B - W$

where $T = M \cdot g$ $M = 10 \cdot \text{kg}$ $F_B = \rho \cdot g \cdot \frac{V}{2}$ $W = SG \cdot \rho \cdot g \cdot V$

Hence $M \cdot g + \rho \cdot g \cdot \frac{V}{2} - SG \cdot \rho \cdot g \cdot V = 0$ $SG = \frac{M}{\rho \cdot V} + \frac{1}{2}$

$$SG = 10 \cdot \text{kg} \times \frac{\text{m}^3}{1000 \cdot \text{kg}} \times \frac{1}{0.025 \cdot \text{m}^3} + \frac{1}{2} \quad SG = 0.9$$

The specific weight is $\gamma = \frac{\text{Weight}}{\text{Volume}} = \frac{SG \cdot \rho \cdot g \cdot V}{V} = SG \cdot \rho \cdot g$ $\gamma = 0.9 \times 1000 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}}$ $\gamma = 8829 \cdot \frac{\text{N}}{\text{m}^3}$

For the equilibrium position when floating, we repeat the force balance with $T = 0$

$$F_B - W = 0 \quad W = F_B \quad \text{with} \quad F_B = \rho \cdot g \cdot V_{\text{submerged}}$$

From references (trying Googling "partial sphere volume") $V_{\text{submerged}} = \frac{\pi \cdot h^2}{3} \cdot (3 \cdot R - h)$

where h is submerged depth and R is the sphere radius $R = \left(\frac{3 \cdot V}{4 \cdot \pi} \right)^{\frac{1}{3}}$ $R = \left(\frac{3}{4 \cdot \pi} \cdot 0.025 \cdot \text{m}^3 \right)^{\frac{1}{3}}$ $R = 0.181 \text{ m}$

Hence $W = SG \cdot \rho \cdot g \cdot V = F_B = \rho \cdot g \cdot \frac{\pi \cdot h^2}{3} \cdot (3 \cdot R - h)$ $h^2 \cdot (3 \cdot R - h) = \frac{3 \cdot SG \cdot V}{\pi}$

$$h^2 \cdot (3 \cdot 0.181 \cdot \text{m} - h) = \frac{3 \cdot 0.9 \cdot 0.025 \cdot \text{m}^3}{\pi} \quad h^2 \cdot (0.544 - h) = 0.0215$$

This is a cubic equation for h . We can keep guessing h values, manually iterate, or use Excel's Goal Seek to find $h = 0.292 \cdot \text{m}$

Problem 3.74

[Difficulty: 2]

3.74 The fat-to-muscle ratio of a person may be determined from a specific gravity measurement. The measurement is made by immersing the body in a tank of water and measuring the net weight. Develop an expression for the specific gravity of a person in terms of their weight in air, net weight in water, and $SG = f(T)$ for water.

Given: Specific gravity of a person is to be determined from measurements of weight in air and the net weight when totally immersed in water.

Find: Expression for the specific gravity of a person from the measurements.

Solution: We will apply the hydrostatics equations to this system.

Governing Equation: $F_{\text{buoy}} = \rho \cdot g \cdot V_d$ (Buoyant force is equal to weight of displaced fluid)

Assumptions: (1) Static fluid
(2) Incompressible fluid

Taking a free body diagram of the body: $\Sigma F_y = 0 \quad F_{\text{net}} - M \cdot g + F_{\text{buoy}} = 0$

F_{net} is the weight measurement for the immersed body.

$F_{\text{net}} = M \cdot g - F_{\text{buoy}} = M \cdot g - \rho_w \cdot g \cdot V_d$ However in air: $F_{\text{air}} = M \cdot g$

Therefore the weight measured in water is: $F_{\text{net}} = F_{\text{air}} - \rho_w \cdot g \cdot V_d$ and $V_d = \frac{F_{\text{air}} - F_{\text{net}}}{\rho_w \cdot g}$

Now in order to find the specific gravity of the person, we need his/her density:

$F_{\text{air}} = M \cdot g = \rho \cdot g \cdot V_d = \rho \cdot g \cdot \frac{(F_{\text{air}} - F_{\text{net}})}{\rho_w \cdot g}$ Simplifying this expression we get: $F_{\text{air}} = \frac{\rho}{\rho_w} (F_{\text{air}} - F_{\text{net}})$

Now if we call the density of water at 4 deg C ρ_{w4C} then: $F_{\text{air}} = \left(\frac{\rho}{\rho_{w4C}} \right) (F_{\text{air}} - F_{\text{net}}) = \frac{SG}{SG_w} \cdot (F_{\text{air}} - F_{\text{net}})$

Solving this expression for the specific gravity of the person SG, we get: $SG = SG_w \cdot \frac{F_{\text{air}}}{F_{\text{air}} - F_{\text{net}}}$

Problem 3.75

[Difficulty: 2]

3.75 An open tank is filled to the top with water. A steel cylindrical container, wall thickness $\delta = 1$ mm, outside diameter $D = 100$ mm, and height $H = 1$ m, with an open top, is gently placed in the water. What is the volume of water that overflows from the tank? How many 1 kg weights must be placed in the container to make it sink? Neglect surface tension effects.

Given: Geometry of steel cylinder

Find: Volume of water displaced; number of 1 kg wts to make it sink

Solution:

The data is For water $\rho = 999 \cdot \frac{\text{kg}}{\text{m}^3}$

For steel $SG = 7.83$

For the cylinder $D = 100 \cdot \text{mm}$ $H = 1 \cdot \text{m}$ $\delta = 1 \cdot \text{mm}$

The volume of the cylinder is $V_{\text{steel}} = \delta \cdot \left(\frac{\pi \cdot D^2}{4} + \pi \cdot D \cdot H \right)$ $V_{\text{steel}} = 3.22 \times 10^{-4} \cdot \text{m}^3$

The weight of the cylinder is $W = SG \cdot \rho \cdot g \cdot V_{\text{steel}}$

$$W = 7.83 \times 999 \cdot \frac{\text{kg}}{\text{m}^3} \times 9.81 \cdot \frac{\text{m}}{\text{s}^2} \times 3.22 \times 10^{-4} \cdot \text{m}^3 \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad W = 24.7 \text{ N}$$

At equilibrium, the weight of fluid displaced is equal to the weight of the cylinder

$$W_{\text{displaced}} = \rho \cdot g \cdot V_{\text{displaced}} = W$$

$$V_{\text{displaced}} = \frac{W}{\rho \cdot g} = 24.7 \cdot \text{N} \times \frac{\text{m}^3}{999 \cdot \text{kg}} \times \frac{\text{s}^2}{9.81 \cdot \text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{N} \cdot \text{s}^2} \quad V_{\text{displaced}} = 2.52 \text{ L}$$

To determine how many 1 kg wts will make it sink, we first need to find the extra volume that will need to be displaced

Distance cylinder sank $x_1 = \frac{V_{\text{displaced}}}{\left(\frac{\pi \cdot D^2}{4} \right)}$ $x_1 = 0.321 \text{ m}$

Hence, the cylinder must be made to sink an additional distance $x_2 = H - x_1$ $x_2 = 0.679 \text{ m}$

We need to add n weights so that $1 \cdot \text{kg} \cdot n \cdot g = \rho \cdot g \cdot \frac{\pi \cdot D^2}{4} \cdot x_2$

$$n = \frac{\rho \cdot \pi \cdot D^2 \cdot x_2}{4 \times 1 \cdot \text{kg}} = 999 \cdot \frac{\text{kg}}{\text{m}^3} \times \frac{\pi}{4} \times (0.1 \cdot \text{m})^2 \times 0.679 \cdot \text{m} \times \frac{1}{1 \cdot \text{kg}} \times \frac{\text{N} \cdot \text{s}^2}{\text{kg} \cdot \text{m}} \quad n = 5.33$$

Hence we need $n = 6$ weights to sink the cylinder

Problem 3.76

(Difficulty: 2)

3.76 If the timber weighs 670 N , calculate its angle of inclination when the water surface is 2.1 m above the pivot. Above what depth will the timber stand vertically?

Find: Above what depth will the timber stand vertically.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

The buoyancy force is:

$$F_b = \gamma_{\text{water}} V = 0.152\text{ m} \times 0.152\text{ m} \times x\text{ m} \times 9810 \frac{\text{N}}{\text{m}^3} = 226.7x\text{ (N)}$$

Take the moment about pivot we have:

$$M = W \times 0.5 \times 3.6\text{ m} \cos \theta - \frac{x}{2}\text{ m} \times F_b \cos \theta = 0$$

$$670\text{ N} \times 0.5 \times 3.6\text{ m} \times \cos \theta - \frac{x}{2}\text{ m} \times 226.7x \times \cos \theta = 0$$

Solving this equation we have:

$$x = 3.26\text{ m}$$

The angle when water surface $y = 2.1\text{ m}$ is:

$$\theta = \sin^{-1} \left(\frac{2.1\text{ m}}{3.26\text{ m}} \right) = 40.1^\circ$$

We have the following relation:

$$x = \frac{y}{\sin \theta}$$

Substitute in to the momentum we have:

$$670 \text{ N} \times 0.5 \times 3.6 \text{ m} - \frac{y}{2\sin \theta} \text{ m} \times 226.7 \frac{y}{\sin \theta} = 0$$

If the timber is vertically, we have:

$$\theta = 90^\circ$$

$$\sin 90^\circ = 1$$

So we have:

$$670 \text{ N} \times 0.5 \times 3.6 \text{ m} - \frac{y}{2} \text{ m} \times 226.7 y = 0$$

Solving this equation we have:

$$y = 3.26 \text{ m}$$

When the water surface is $y = 3.26 \text{ m}$, the timber will stand vertically.

Problem 3.77

(Difficulty: 2)

3.77 The barge shown weighs 40 *tons* and carries a cargo of 40 *tons*. Calculate its draft in freshwater.

Find: The draft, where the draft is the depth to which the barge sinks.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

For the barge floating in water we have the buoyancy force as:

$$F_B = \gamma_{water} V = W$$

The weight of the barge is:

$$W = (40 + 40) \text{ tons} = 80 \text{ tons} \times \frac{2000 \text{ lbf}}{\text{ton}} = 160000 \text{ lbf}$$

The volume of water displaced is then:

$$V = \frac{W}{\gamma_{water}} = \frac{160000 \text{ lbf}}{62.4 \frac{\text{lbf}}{\text{ft}^3}} = 2564 \text{ ft}^3$$

The volume in terms of the draft d is:

$$V = A_c L = \left(40 \text{ ft} + 40 \text{ ft} + 2 \times \frac{5}{8} d \right) \times \frac{d}{2} \times 20 \text{ ft} = 800d + 12.5d^2$$

Thus we have the relation:

$$800d + 12.5d^2 = 2564$$

Solving this equation we have for the draft:

$$d = 3.06 \text{ ft}$$

Problem 3.78

[Difficulty: 2]

3.78 Quantify the experiment performed by Archimedes to identify the material content of King Hiero's crown. Assume you can measure the weight of the king's crown in air, W_a , and the weight in water, W_w . Express the specific gravity of the crown as a function of these measured values.

Given: Experiment performed by Archimedes to identify the material content of King Hiero's crown. The crown was weighed in air and in water.

Find: Expression for the specific gravity of the crown as a function of the weights in water and air.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $F_b = \rho \cdot g \cdot V_d$ (Buoyant force is equal to weight of displaced fluid)

Assumptions: (1) Static fluid
(2) Incompressible fluid

Taking a free body diagram of the body: $\Sigma F_z = 0$ $W_w - M \cdot g + F_b = 0$

W_w is the weight of the crown in water.

$W_w = M \cdot g - F_{\text{buoy}} = M \cdot g - \rho_w \cdot g \cdot V_d$ However in air: $W_a = M \cdot g$

Therefore the weight measured in water is: $W_w = W_a - \rho_w \cdot g \cdot V_d$

so the volume is: $V_d = \frac{W_a - W_w}{\rho_w \cdot g}$ Now the density of the crown is: $\rho_c = \frac{M}{V_d} = \frac{M \cdot \rho_w \cdot g}{W_a - W_w} = \frac{W_a}{W_a - W_w} \cdot \rho_w$

Therefore, the specific gravity of the crown is: $SG = \frac{\rho_c}{\rho_w} = \frac{W_a}{W_a - W_w}$ $SG = \frac{W_a}{W_a - W_w}$

Note: by definition specific gravity is the density of an object divided by the density of water at 4 degrees Celsius, so the measured temperature of the water in the experiment and the data from tables A.7 or A.8 may be used to correct for the variation in density of the water with temperature.

Problem 3.79

[Difficulty: 2]

3.79 Hot-air ballooning is a popular sport. According to a recent article, “hot-air volumes must be large because air heated to 150°F over ambient lifts only 0.018 lbf/ft³ compared to 0.066 and 0.071 for helium and hydrogen, respectively.” Check these statements for sea-level conditions. Calculate the effect of increasing the hot-air maximum temperature to 250°F above ambient.

Given: Balloons with hot air, helium and hydrogen. Claim lift per cubic foot of 0.018, 0.066, and 0.071 pounds force per cubic foot for respective gases, with the air heated to 150 deg. F over ambient.

Find: (a) evaluate the claims of lift per unit volume
(b) determine change in lift when air is heated to 250 deg. F over ambient.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $L = \rho_a \cdot g \cdot V - \rho_g \cdot g \cdot V$ (Net lift force is equal to difference in weights of air and gas)

$$p = \rho \cdot R \cdot T \quad \text{(Ideal gas equation of state)}$$

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Ideal gas behavior

The lift per unit volume may be written as: $LV = \frac{L}{V} = g \cdot (\rho_a - \rho_g) = \rho_a \cdot g \cdot \left(1 - \frac{\rho_g}{\rho_a}\right)$ now if we take the ideal gas equation and

we take into account that the pressure inside and outside the balloon are equal: $\frac{L}{V} = \rho_a \cdot g \cdot \left(1 - \frac{R_a \cdot T_a}{R_g \cdot T_g}\right) = \gamma_a \cdot \left(1 - \frac{R_a \cdot T_a}{R_g \cdot T_g}\right)$

At standard conditions the specific weight of air is: $\gamma_a = 0.0765 \cdot \frac{\text{lbf}}{\text{ft}^3}$ the gas constant is: $R_a = 53.33 \cdot \frac{\text{ft} \cdot \text{lbf}}{\text{lbm} \cdot \text{R}}$ and $T_a = 519 \cdot \text{R}$

For helium: $R_g = 386.1 \cdot \frac{\text{ft} \cdot \text{lbf}}{\text{lbm} \cdot \text{R}}$ $T_g = T_a$ and therefore: $LV_{\text{He}} = 0.0765 \cdot \frac{\text{lbf}}{\text{ft}^3} \times \left(1 - \frac{53.33}{386.1}\right)$ $LV_{\text{He}} = 0.0659 \cdot \frac{\text{lbf}}{\text{ft}^3}$

For hydrogen: $R_g = 766.5 \cdot \frac{\text{ft} \cdot \text{lbf}}{\text{lbm} \cdot \text{R}}$ $T_g = T_a$ and therefore: $LV_{\text{H}_2} = 0.0765 \cdot \frac{\text{lbf}}{\text{ft}^3} \times \left(1 - \frac{53.33}{766.5}\right)$ $LV_{\text{H}_2} = 0.0712 \cdot \frac{\text{lbf}}{\text{ft}^3}$

For hot air at 150 degrees above ambient:

$$R_g = R_a \quad T_g = T_a + 150 \cdot \text{R} \quad \text{and therefore:} \quad LV_{\text{air150}} = 0.0765 \cdot \frac{\text{lbf}}{\text{ft}^3} \times \left(1 - \frac{519}{519 + 150}\right) \quad LV_{\text{air150}} = 0.0172 \cdot \frac{\text{lbf}}{\text{ft}^3}$$

The agreement with the claims stated above is good.

For hot air at 250 degrees above ambient:

$$R_g = R_a \quad T_g = T_a + 250 \cdot \text{R} \quad \text{and therefore:} \quad LV_{\text{air250}} = 0.0765 \cdot \frac{\text{lbf}}{\text{ft}^3} \times \left(1 - \frac{519}{519 + 250}\right) \quad LV_{\text{air250}} = 0.0249 \cdot \frac{\text{lbf}}{\text{ft}^3}$$

$$\frac{LV_{\text{air250}}}{LV_{\text{air150}}} = 1.450 \quad \text{Air at } \Delta T \text{ of 250 deg. F gives 45\% more lift than air at } \Delta T \text{ of 150 deg. F!}$$

Problem 3.80

[Difficulty: 3]

3.80 It is desired to use a hot air balloon with a volume of 320,000 ft³ for rides planned in summer morning hours when the air temperature is about 48°F. The torch will warm the air inside the balloon to a temperature of 160°F. Both inside and outside pressures will be “standard” (14.7 psia). How much mass can be carried by the balloon (basket, fuel, passengers, personal items, and the component of the balloon itself) if neutral buoyancy is to be assured? What mass can be carried by the balloon to ensure vertical takeoff acceleration of 2.5 ft/s²? For this, consider that both balloon and inside air have to be accelerated, as well as some of the surrounding air (to make way for the balloon). The rule of thumb is that the total mass subject to acceleration is the mass of the balloon, all its appurtenances, and twice its volume of air. Given that the volume of hot air is fixed during the flight, what can the balloonists do when they want to go down?

Given: Data on hot air balloon

Find: Maximum mass of balloon for neutral buoyancy; mass for initial acceleration of 2.5 ft/s².

Assumptions: Air is treated as static and incompressible, and an ideal gas

Solution:

Basic equation $F_B = \rho_{\text{atm}} \cdot g \cdot V$ and $\Sigma F_y = M \cdot a_y$

Hence $\Sigma F_y = 0 = F_B - W_{\text{hotair}} - W_{\text{load}} = \rho_{\text{atm}} \cdot g \cdot V - \rho_{\text{hotair}} \cdot g \cdot V - M \cdot g$ for neutral buoyancy

$$M = V \cdot (\rho_{\text{atm}} - \rho_{\text{hotair}}) = \frac{V \cdot p_{\text{atm}}}{R} \cdot \left(\frac{1}{T_{\text{atm}}} - \frac{1}{T_{\text{hotair}}} \right)$$

$$M = 320000 \cdot \text{ft}^3 \times 14.7 \cdot \frac{\text{lbf}}{\text{in}^2} \times \left(\frac{12 \cdot \text{in}}{\text{ft}} \right)^2 \times \frac{\text{lbm} \cdot \text{R}}{53.33 \cdot \text{ft} \cdot \text{lbf}} \times \left[\frac{1}{(48 + 460) \cdot \text{R}} - \frac{1}{(160 + 460) \cdot \text{R}} \right] \quad M = 4517 \cdot \text{lbm}$$

Initial acceleration $\Sigma F_y = F_B - W_{\text{hotair}} - W_{\text{load}} = (\rho_{\text{atm}} - \rho_{\text{hotair}}) \cdot g \cdot V - M_{\text{new}} \cdot g = M_{\text{accel}} \cdot a = (M_{\text{new}} + 2 \cdot \rho_{\text{hotair}} \cdot V) \cdot a$

Solving for M_{new} $(\rho_{\text{atm}} - \rho_{\text{hotair}}) \cdot g \cdot V - M_{\text{new}} \cdot g = (M_{\text{new}} + 2 \cdot \rho_{\text{hotair}} \cdot V) \cdot a$

$$M_{\text{new}} = V \cdot \frac{(\rho_{\text{atm}} - \rho_{\text{hotair}}) \cdot g - 2 \cdot \rho_{\text{hotair}} \cdot a}{a + g} = \frac{V \cdot p_{\text{atm}}}{a + g} \cdot \left[g \cdot \left(\frac{1}{T_{\text{atm}}} - \frac{1}{T_{\text{hotair}}} \right) - \frac{2 \cdot a}{T_{\text{hotair}}} \right]$$

$$M_{\text{new}} = 320000 \cdot \text{ft}^3 \cdot 14.7 \cdot \frac{\text{lbf}}{\text{in}^2} \cdot \left(\frac{12 \cdot \text{in}}{\text{ft}} \right)^2 \cdot \frac{\text{lbm} \cdot \text{R}}{53.33 \cdot \text{ft} \cdot \text{lbf}} \cdot \frac{\text{s}^2}{(2.5 + 32.2) \cdot \text{ft}} \cdot \left[32.2 \cdot \left[\frac{1}{(48 + 460)} - \frac{1}{(160 + 460)} \right] - 2 \cdot 2.5 \cdot \frac{1}{(160 + 460)} \right] \cdot \frac{\text{ft}}{\text{s}^2 \cdot \text{R}}$$

$$M_{\text{new}} = 1239 \cdot \text{lbm}$$

To make the balloon move up or down during flight, the air needs to be heated to a higher temperature, or let cool (or let in ambient air).

Problem 3.81

(Difficulty: 2)

3.81 The opening in the bottom of the tank is square and slightly less than 2 ft on each side. The opening is to be plugged with a wooden cube 2 ft on a side.

(a) What weight W should be attached to the wooden cube to insure successful plugging of the hole?

The wood weighs $40 \frac{\text{lb}_f}{\text{ft}^3}$,

(b) What upward force must be exerted on the block to lift it and allow water to drain from the tank?

Find: The weight of the block and the force needed to lift it

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

(a) Because the wood bottom surface is in the atmosphere so the pressure on the bottom surface is zero in this case and there is no buoyancy force. The force acting on the wood cube in the vertical direction is:

$$F_V = F_p + G$$

$$F_V = \gamma h_1 A + G = 62.4 \frac{\text{lb}_f}{\text{ft}^3} \times 5\text{ ft} \times 2\text{ ft} \times 2\text{ ft} + 40 \frac{\text{lb}_f}{\text{ft}^3} \times (2\text{ ft})^3 = 1568\text{ lb}_f$$

The direction of F_V is downward. So we do not need any weight W attached to the wood cube.

(b) To lift the block, we need a force larger than F_V , so we have:

$$F_{up} \geq F_V = 1568 \text{ lbf}$$

Problem 3.82

(Difficulty: 2)

3.82 A balloon has a weight (including crew but not gas) of 2.2 kN and a gas-bag capacity of 566 m^3 . At the ground it is (partially) inflated with 445 N of helium. How high can this balloon rise in the U.S standard atmosphere if the helium always assumes the pressure and temperature of the atmosphere?

Find: How high this balloon will rise.

Assumptions: Fluid is incompressible and static

Solution: Apply the hydrostatic relations:

Pressure as a function of depth

$$\Delta p = \rho g h$$

Buoyancy force:

$$F_b = \rho g V$$

At the sea level, for helium we have:

$$p = 101.3 \text{ kPa}$$

$$T = 288 \text{ K}$$

$$R = 2076.8 \frac{\text{J}}{\text{kg} \cdot \text{K}}$$

According to the ideal gas law:

$$\rho_h = \frac{p}{RT} = \frac{101.3 \text{ kPa}}{2076.8 \frac{\text{J}}{\text{kg} \cdot \text{K}} \times 288 \text{ K}} = 0.1694 \frac{\text{kg}}{\text{m}^3}$$

$$\gamma_h = \rho g = 0.1694 \frac{\text{kg}}{\text{m}^3} \times 9.81 \frac{\text{m}}{\text{s}^2} = 1.662 \frac{\text{N}}{\text{m}^3}$$

The volume of the helium is:

$$V_h = \frac{W_h}{\gamma_h} = \frac{445 \text{ N}}{1.662 \frac{\text{N}}{\text{m}^3}} = 268 \text{ m}^3$$

The buoyancy force is calculated by:

$$F_B = \gamma_{air} V_b$$

The weight of the whole balloon is:

$$W = 2.2 \text{ kN} + W_h$$

We have the following table as (the helium always has the same temperature and pressure as the atmosphere):

Altitude (km)	Pressure (kPa)	Temperature (K)	$\forall (m^3)$	$\gamma_{air} \left(\frac{N}{m^3} \right)$	$W_h (kN)$	$F_B (kN)$	$W (kN)$
6	47.22	249.2	497	6.46	0.445	3.21	2.65
8	35.70	236.3	566	5.14	0.402	2.91	2.60
10	26.50	223.4	566	4.04	0.317	2.29	2.52

When the maximum volume of the helium is reached, the volume will become a constant for helium.

Equilibrium is reached as:

$$F_B = W$$

At 8 km we have:

$$F_B - W = 0.31 \text{ kN}$$

At 10 km we have:

$$F_B - W = -0.23 \text{ kN}$$

With the interpolation we have the height for equilibrium as:

$$h = 8 \text{ km} + 2 \text{ km} \times \frac{0.31}{0.31 + 0.23} = 9.15 \text{ km}$$

Problem 3.83

[Difficulty: 3]

3.83 A helium balloon is to lift a payload to an altitude of 40 km, where the atmospheric pressure and temperature are 3.0 mbar and -25°C , respectively. The balloon skin is polyester with specific gravity of 1.28 and thickness of 0.015 mm. To maintain a spherical shape, the balloon is pressurized to a gage pressure of 0.45 mbar. Determine the maximum balloon diameter if the allowable tensile stress in the skin is limited to 62 MN/m^2 . What payload can be carried?

Given: A pressurized balloon is to be designed to lift a payload of mass M to an altitude of 40 km, where $p = 3.0 \text{ mbar}$ and $T = -25^{\circ}\text{C}$. The balloon skin has a specific gravity of 1.28 and thickness 0.015 mm. The gage pressure of the helium is 0.45 mbar. The allowable tensile stress in the balloon is 62 MN/m^2

Find: (a) The maximum balloon diameter
(b) The maximum payload mass

Solution: We will apply the hydrostatics equations to this system.

Governing Equations:

$$F_{\text{buoy}} = \rho \cdot g \cdot V_d \quad (\text{Buoyant force is equal to mass of displaced fluid})$$

$$p = \rho \cdot R \cdot T \quad (\text{Ideal gas equation of state})$$

Assumptions:

- (1) Static, incompressible fluid
- (2) Static equilibrium at 40 km altitude
- (3) Ideal gas behavior

The diameter of the balloon is limited by the allowable tensile stress in the skin:

$$\Sigma F = \frac{\pi}{4} \cdot D^2 \cdot \Delta p - \pi \cdot D \cdot t \cdot \sigma = 0 \quad \text{Solving this expression for the diameter:} \quad D_{\text{max}} = \frac{4 \cdot t \cdot \sigma}{\Delta p}$$

$$D_{\text{max}} = 4 \times 0.015 \times 10^{-3} \cdot \text{m} \times 62 \times 10^6 \cdot \frac{\text{N}}{\text{m}^2} \times \frac{1}{0.45 \times 10^{-3} \cdot \text{bar}} \times \frac{\text{bar} \cdot \text{m}^2}{10^5 \cdot \text{N}} \quad D_{\text{max}} = 82.7 \text{ m}$$

To find the maximum allowable payload we perform a force balance on the system:

$$\Sigma F_z = F_{\text{buoy}} - M_{\text{He}} \cdot g - M_b \cdot g - M \cdot g = 0 \quad \rho_a \cdot g \cdot V_b - \rho_{\text{He}} \cdot g \cdot V_b - \rho_s \cdot g \cdot V_s - M \cdot g = 0$$

Solving for M : $M = (\rho_a - \rho_{\text{He}}) \cdot V_b - \rho_s \cdot V_s$ The volume of the balloon is: $V_b = \frac{\pi}{6} \cdot D^3$

The volume of the skin is: $V_s = \pi \cdot D^2 \cdot t$ Therefore, the mass is: $M = \frac{\pi}{6} \cdot (\rho_a - \rho_{\text{He}}) \cdot D^3 - \pi \cdot \rho_s \cdot D^2 \cdot t$

The air density: $\rho_a = \frac{p_a}{R_a \cdot T} \quad \rho_a = 3.0 \times 10^{-3} \cdot \text{bar} \times \frac{\text{kg} \cdot \text{K}}{287 \cdot \text{N} \cdot \text{m}} \times \frac{1}{(273 - 25) \cdot \text{K}} \times \frac{10^5 \cdot \text{N}}{\text{bar} \cdot \text{m}^2} \quad \rho_a = 4.215 \times 10^{-3} \frac{\text{kg}}{\text{m}^3}$

Repeating for helium: $\rho_{\text{He}} = \frac{p}{R \cdot T} \quad \rho_{\text{He}} = 6.688 \times 10^{-4} \frac{\text{kg}}{\text{m}^3}$

The payload mass is: $M = \frac{\pi}{6} \times (4.215 - 0.6688) \times 10^{-3} \cdot \frac{\text{kg}}{\text{m}^3} \times (82.7 \text{ m})^3 - \pi \times 1.28 \times 10^3 \cdot \frac{\text{kg}}{\text{m}^3} \times (82.7 \text{ m})^2 \times 0.015 \times 10^{-3} \cdot \text{m}$

$$M = 638 \text{ kg}$$

Problem 3.84

[Difficulty: 3]

3.84 The stem of a glass hydrometer used to measure specific gravity is 5 mm in diameter. The distance between marks on the stem is 2 mm per 0.1 increment of specific gravity. Calculate the magnitude and direction of the error introduced by surface tension if the hydrometer floats in kerosene. (Assume the contact angle between kerosene and glass is 0° .)

Given: Glass hydrometer used to measure SG of liquids. Stem has diameter $D=5$ mm, distance between marks on stem is $d=2$ mm per 0.1 SG. Hydrometer floats in kerosene (Assume zero contact angle between glass and kerosene).

Find: Magnitude of error introduced by surface tension.

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $F_{\text{buoy}} = \rho \cdot g \cdot V_d$ (Buoyant force is equal to weight of displaced fluid)

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Zero contact angle between ethyl alcohol and glass

The surface tension will cause the hydrometer to sink Δh lower into the liquid. Thus for this change:

$$\Sigma F_z = \Delta F_{\text{buoy}} - F_\sigma = 0$$

The change in buoyant force is: $\Delta F_{\text{buoy}} = \rho \cdot g \cdot \Delta V = \rho \cdot g \cdot \frac{\pi}{4} \cdot D^2 \cdot \Delta h$

The force due to surface tension is: $F_\sigma = \pi \cdot D \cdot \sigma \cdot \cos(\theta) = \pi \cdot D \cdot \sigma$

Thus, $\rho \cdot g \cdot \frac{\pi}{4} \cdot D^2 \cdot \Delta h = \pi \cdot D \cdot \sigma$ Upon simplification: $\frac{\rho \cdot g \cdot D \cdot \Delta h}{4} = \sigma$

Solving for Δh : $\Delta h = \frac{4 \cdot \sigma}{\rho \cdot g \cdot D}$ From Table A.2, $\text{SG} = 1.43$ and from Table A.4, $\sigma = 26.8 \text{ mN/m}$

Therefore, $\Delta h = 4 \times 26.8 \times 10^{-3} \frac{\text{N}}{\text{m}} \times \frac{\text{m}^3}{1430 \cdot \text{kg}} \times \frac{\text{s}^2}{9.81 \cdot \text{m}} \times \frac{1}{5 \times 10^{-3} \cdot \text{m}} \times \frac{\text{kg} \cdot \text{m}}{\text{s}^2 \cdot \text{N}} \Delta h = 1.53 \times 10^{-3} \text{ m}$

So the change in specific gravity will be: $\Delta \text{SG} = 1.53 \times 10^{-3} \cdot \text{m} \times \frac{0.1}{2 \times 10^{-3} \cdot \text{m}} \quad \Delta \text{SG} = 0.0765$

From the diagram, surface tension acts to cause the hydrometer to float lower in the liquid. Therefore, surface tension results in an indicated specific gravity smaller than the actual specific gravity.

Problem 3.85

[Difficulty:4]

3.85 A sphere, of radius R , is partially immersed, to depth d , in a liquid of specific gravity SG . Obtain an algebraic expression for the buoyancy force acting on the sphere as a function of submersion depth d . Plot the results over the range of water depth $0 \leq d \leq 2R$.

Given: Sphere partially immersed in a liquid of specific gravity SG .

Find: (a) Formula for buoyancy force as a function of the submersion depth d
(b) Plot of results over range of liquid depth

Solution: We will apply the hydrostatics equations to this system.

Governing Equations: $F_{\text{buoy}} = \rho \cdot g \cdot V_d$ (Buoyant force is equal to weight of displaced fluid)

Assumptions: (1) Static fluid
(2) Incompressible fluid
(3) Atmospheric pressure acts everywhere

We need an expression for the displaced volume of fluid at an arbitrary depth d . From the diagram we see that:

$$d = R(1 - \cos(\theta_{\text{max}})) \quad \text{at an arbitrary depth } h: \quad h = d - R \cdot (1 - \cos(\theta)) \quad r = R \cdot \sin(\theta)$$

So if we want to find the volume of the submerged portion of the sphere we calculate:

$$V_d = \int_0^{\theta_{\text{max}}} \pi r^2 dh = \pi \int_0^{\theta_{\text{max}}} R^2 \cdot (\sin(\theta))^2 \cdot R \cdot \sin(\theta) d\theta = \pi \cdot R^3 \cdot \int_0^{\theta_{\text{max}}} (\sin(\theta))^3 d\theta \quad \text{Evaluating the integral we get:}$$

$$V_d = \pi \cdot R^3 \cdot \left[\frac{(\cos(\theta_{\text{max}}))^3}{3} - \cos(\theta_{\text{max}}) + \frac{2}{3} \right] \quad \text{Now since: } \cos(\theta_{\text{max}}) = 1 - \frac{d}{R} \text{ we get: } V_d = \pi \cdot R^3 \cdot \left[\frac{1}{3} \left(1 - \frac{d}{R} \right)^3 - \left(1 - \frac{d}{R} \right) + \frac{2}{3} \right]$$

$$\text{Thus the buoyant force is: } F_{\text{buoy}} = \rho_w \cdot SG \cdot g \cdot \pi \cdot R^3 \cdot \left[\frac{1}{3} \left(1 - \frac{d}{R} \right)^3 - \left(1 - \frac{d}{R} \right) + \frac{2}{3} \right]$$

If we non-dimensionalize by the force on a fully submerged sphere:

$$F_d = \frac{F_{\text{buoy}}}{\rho_w \cdot SG \cdot g \cdot \frac{4}{3} \cdot \pi \cdot R^3} = \frac{3}{4} \left[\frac{1}{3} \left(1 - \frac{d}{R} \right)^3 - \left(1 - \frac{d}{R} \right) + \frac{2}{3} \right] \quad F_d = \frac{3}{4} \left[\frac{1}{3} \left(1 - \frac{d}{R} \right)^3 - \left(1 - \frac{d}{R} \right) + \frac{2}{3} \right]$$

Problem 3.86

[Difficulty: 4]

3.86 A sphere of radius 1 in., made from material of specific gravity of $SG = 0.95$, is submerged in a tank of water. The sphere is placed over a hole of radius 0.075 in., in the tank bottom. When the sphere is released, will it stay on the bottom of the tank or float to the surface?

Given: Data on sphere and tank bottom

Find: Expression for SG of sphere at which it will float to surface; minimum SG to remain in position

Assumptions: (1) Water is static and incompressible
(2) Sphere is much larger than the hole at the bottom of the tank

Solution:

Basic equations $F_B = \rho \cdot g \cdot V$ and $\Sigma F_y = F_L - F_U + F_B - W$

where $F_L = p_{\text{atm}} \cdot \pi \cdot a^2$ $F_U = [p_{\text{atm}} + \rho \cdot g \cdot (H - 2 \cdot R)] \cdot \pi \cdot a^2$

$F_B = \rho \cdot g \cdot V_{\text{net}}$ $V_{\text{net}} = \frac{4}{3} \cdot \pi \cdot R^3 - \pi \cdot a^2 \cdot 2 \cdot R$

$W = SG \cdot \rho \cdot g \cdot V$ with $V = \frac{4}{3} \cdot \pi \cdot R^3$

Now if the sum of the vertical forces is positive, the sphere will float away, while if the sum is zero or negative the sphere will stay at the bottom of the tank (its weight and the hydrostatic force are greater than the buoyant force).

Hence $\Sigma F_y = p_{\text{atm}} \cdot \pi \cdot a^2 - [p_{\text{atm}} + \rho \cdot g \cdot (H - 2 \cdot R)] \cdot \pi \cdot a^2 + \rho \cdot g \cdot \left(\frac{4}{3} \cdot \pi \cdot R^3 - 2 \cdot \pi \cdot R \cdot a^2 \right) - SG \cdot \rho \cdot g \cdot \frac{4}{3} \cdot \pi \cdot R^3$

This expression simplifies to $\Sigma F_y = \pi \cdot \rho \cdot g \cdot \left[(1 - SG) \cdot \frac{4}{3} \cdot R^3 - H \cdot a^2 \right]$

$$\Sigma F_y = \pi \times 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \times 32.2 \cdot \frac{\text{ft}}{\text{s}^2} \times \left[\frac{4}{3} \times (1 - 0.95) \times \left(1 \cdot \text{in} \times \frac{\text{ft}}{12 \cdot \text{in}} \right)^3 - 2.5 \cdot \text{ft} \times \left(0.075 \cdot \text{in} \times \frac{\text{ft}}{12 \cdot \text{in}} \right)^2 \right] \times \frac{\text{lbf} \cdot \text{s}^2}{\text{slug} \cdot \text{ft}}$$

$\Sigma F_y = -0.012 \cdot \text{lbf}$ Therefore, the sphere stays at the bottom of the tank.

Problem 3.87

[Difficulty: 3]

3.87 You are in the Bermuda Triangle when you see a bubble plume eruption (a large mass of air bubbles, similar to a foam) off to the side of the boat. Do you want to head toward it and be part of the action? What is the effective density of the water and air bubbles in the drawing on the right that will cause the boat to sink? Your boat is 10 ft long, and weight is the same in both cases.

Given: Data on boat

Find: Effective density of water/air bubble mix if boat sinks

Solution:

Basic equations $F_B = \rho \cdot g \cdot V$ and $\Sigma F_y = 0$

We can apply the sum of forces for the "floating" free body

$$\Sigma F_y = 0 = F_B - W \quad \text{where} \quad F_B = SG_{\text{sea}} \cdot \rho \cdot g \cdot V_{\text{subfloat}}$$

$$V_{\text{subfloat}} = \frac{1}{2} \cdot h \cdot \left(\frac{2 \cdot h}{\tan \theta} \right) \cdot L = \frac{L \cdot h^2}{\tan(\theta)} \quad SG_{\text{sea}} = 1.024 \quad (\text{Table A.2})$$

Hence
$$W = \frac{SG_{\text{sea}} \cdot \rho \cdot g \cdot L \cdot h^2}{\tan(\theta)} \quad (1)$$

We can apply the sum of forces for the "sinking" free body

$$\Sigma F_y = 0 = F_B - W \quad \text{where} \quad F_B = SG_{\text{mix}} \cdot \rho \cdot g \cdot V_{\text{sub}} \quad V_{\text{subsink}} = \frac{1}{2} \cdot H \cdot \left(\frac{2 \cdot H}{\tan \theta} \right) \cdot L = \frac{L \cdot H^2}{\tan(\theta)}$$

Hence
$$W = \frac{SG_{\text{mix}} \cdot \rho \cdot g \cdot L \cdot H^2}{\tan(\theta)} \quad (2)$$

Comparing Eqs. 1 and 2
$$W = \frac{SG_{\text{sea}} \cdot \rho \cdot g \cdot L \cdot h^2}{\tan(\theta)} = \frac{SG_{\text{mix}} \cdot \rho \cdot g \cdot L \cdot H^2}{\tan(\theta)}$$

$$SG_{\text{mix}} = SG_{\text{sea}} \cdot \left(\frac{h}{H} \right)^2 \quad SG_{\text{mix}} = 1.024 \times \left(\frac{7}{8} \right)^2 \quad SG_{\text{mix}} = 0.784$$

The density is
$$\rho_{\text{mix}} = SG_{\text{mix}} \cdot \rho \quad \rho_{\text{mix}} = 0.784 \times 1.94 \cdot \frac{\text{slug}}{\text{ft}^3} \quad \rho_{\text{mix}} = 1.52 \cdot \frac{\text{slug}}{\text{ft}^3}$$

Problem 3.88

[Difficulty: 2]

3.88 Three steel balls (each about half an inch in diameter) lie at the bottom of a plastic shell floating on the water surface in a partially filled bucket. Someone removes the steel balls from the shell and carefully lets them fall to the bottom of the bucket, leaving the plastic shell to float empty. What happens to the water level in the bucket? Does it rise, go down, or remain unchanged? Explain.

Given: Steel balls resting in floating plastic shell in a bucket of water

Find: What happens to water level when balls are dropped in water

Solution: Basic equation $F_B = \rho \cdot V_{\text{disp}} \cdot g = W$ for a floating body weight W

When the balls are in the plastic shell, the shell and balls displace a volume of water equal to their own weight - a large volume because the balls are dense. When the balls are removed from the shell and dropped in the water, the shell now displaces only a small volume of water, and the balls sink, displacing only their own volume. Hence the difference in displaced water before and after moving the balls is the difference between the volume of water that is equal to the weight of the balls, and the volume of the balls themselves. The amount of water displaced is significantly reduced, so the water level in the bucket drops.

Volume displaced before moving balls: $V_1 = \frac{W_{\text{plastic}} + W_{\text{balls}}}{\rho \cdot g}$

Volume displaced after moving balls: $V_2 = \frac{W_{\text{plastic}}}{\rho \cdot g} + V_{\text{balls}}$

Change in volume displaced $\Delta V = V_2 - V_1 = V_{\text{balls}} - \frac{W_{\text{balls}}}{\rho \cdot g} = V_{\text{balls}} - \frac{SG_{\text{balls}} \cdot \rho \cdot g \cdot V_{\text{balls}}}{\rho \cdot g}$

$$\Delta V = V_{\text{balls}} \cdot (1 - SG_{\text{balls}})$$

Hence initially a large volume is displaced; finally a small volume is displaced ($\Delta V < 0$ because $SG_{\text{balls}} > 1$)

Problem 3.89

[Difficulty: 4]

3.89 A proposed ocean salvage scheme involves pumping air into “bags” placed within and around a wrecked vessel on the sea bottom. Comment on the practicality of this plan, supporting your conclusions with analyses.

Open-Ended Problem Statement: A proposed ocean salvage scheme involves pumping air into “bags” placed within and around a wrecked vessel on the sea bottom. Comment on the practicality of this plan, supporting your conclusions with analyses.

Discussion: This plan has several problems that render it impractical. First, pressures at the sea bottom are very high. For example, *Titanic* was found in about 12,000 ft of seawater. The corresponding pressure is nearly 6,000 psi. Compressing air to this pressure is possible, but would require a multi-stage compressor and very high power.

Second, it would be necessary to manage the buoyancy force after the bag and object are broken loose from the sea bed and begin to rise toward the surface. Ambient pressure would decrease as the bag and artifact rise toward the surface. The air would tend to expand as the pressure decreases, thereby tending to increase the volume of the bag. The buoyancy force acting on the bag is directly proportional to the bag volume, so it would increase as the assembly rises. The bag and artifact thus would tend to accelerate as they approach the sea surface. The assembly could broach the water surface with the possibility of damaging the artifact or the assembly.

If the bag were of constant volume, the pressure inside the bag would remain essentially constant at the pressure of the sea floor, e.g., 6,000 psi for *Titanic*. As the ambient pressure decreases, the pressure differential from inside the bag to the surroundings would increase. Eventually the difference would equal sea floor pressure. This probably would cause the bag to rupture.

If the bag permitted some expansion, a control scheme would be needed to vent air from the bag during the trip to the surface to maintain a constant buoyancy force just slightly larger than the weight of the artifact in water. Then the trip to the surface could be completed at low speed without danger of broaching the surface or damaging the artifact.
